A parasite the supposed cause of some cases of epilepsy, G. H. FRENCH (*Canad. Ent.*, 32 (1900), No. 9, pp. 263, 264, fig. 1).—*Gastrophilus epilepsalis* is described as a new species, which was found in great numbers in the intestines of a boy suffering from epileptic spasms. After a prolonged anthelmintic treatment the boy recovered, and it is believed by the author that this species was the direct cause of epilepsy. It is not possible to determine in this case the origin of the infestation.

Statistics on parasites of slaughtered animals of European Russia, Siberia, and the Caucasus for 1896 and 1897, G. GURIN (*Izv. Moscov. Selskokhoz. Inst.*, 5 (1899), No. 3, pp. 254-283).—These statistics are taken from the reports of 40 slaughterhouses and cover 1,959,688 cattle, 149,329 calves, 1,479,923 sheep, 510,842 hogs, and 13,036 horses. The most common parasite in all these animals was *Tenia echinococcus*. The liver fluke was the second most frequent in adult cattle, calves, and sheep. Other parasites which occurred with more or less frequency were *T. medio-canellata*, *T. denticulata*, *T. expansa*, *Strongylus paradoxus*, *S. micrurus*, *S. filaria*, *S. contortus*, *Ascaris megaloccephala*, and *Trichina spiralis*.—P. FIREMAN.

Gregarines and the intestinal epithelium, L. LÉGER and O. DUBOSCQ (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 23, pp. 1566-1568).—The author made a study of the life history of gregarines in the alimentary tracts of insects. The study was principally confined to *Anthrenus museorum* and *Gryllus domesticus*. In the intestines of the former species the gregarine *Pyrrinia möbuszi* was found in abundance, while *Diplocystis major* was the common species in the intestines of the cricket. The author was unable to find these species inside the epithelial cells during any stage of their development.

Nodular disease of the intestines of sheep, D. HUTCHEON (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 2, pp. 89-91).—The author made a study of this disease of sheep. It is stated that no remedies are known which will kill the embryo worms in the intestinal nodules and restore the intestines to a healthy condition. It is possible, however, to expel the worms from the intestines by the use of cathartic remedies.

Worms in sheep (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 1, pp. 22-26).—Brief notes are given on nematode worms in lambs, together with a discussion of the more approved remedies for ridding lambs of these parasites, and methods of preventing infestation.

A biological note on *Gastrophilus equi*, J. ERICSSON (*Ent. Tidskr.*, 21 (1900), No. 1, pp. 47, 48).

Dehorning steers, J. H. GRIDDALE (*Canada Expt. Farms Rpts.* 1899, pp. 58, 59).—The author reports observations upon a number of steers which were dehorned. No definite statement is made as to the exact cost of dehorning, and no decided difference was noted in the effect of different instruments used in the process. These instruments were a saw and 2 forms of patented horn clippers. Some loss of weight was noted during the first few days succeeding the operation, and a corresponding loss of weight was observed in check animals, which were apparently worried by the action of the animals which were dehorned. All animals recovered their original weight within about a month.

A contribution to the study of so-called disinfectant soaps, with special reference to creolin soaps, C. TONZIG (*Extr. Gaz. Osp. e Clin.*, 21 (1900), No. 6, pp. 12).—From experiments conducted with various soaps, to which different disinfectants had been added, the author concludes that simple soaps are not rendered any more effective by the addition of creolin, but that on the contrary they lose a portion of the disinfectant power which they possessed. Corrosive sublimate when added to soaps is transformed into the inert oleate and stearate of mercury, while boric acid and salicylic acid become transformed into soda and potash salts.

STATISTICS—MISCELLANEOUS.

Twenty-third Annual Report of Connecticut State Station, 1899 (*Connecticut State Sta. Rpt.* 1899, pt. 3, pp. I–XV).—These pages contain the organization list of the station, reports of the director and board of control, and a financial statement for the fiscal year ended September 30, 1899.

Eleventh Annual Report of Kentucky Station, 1898 (*Kentucky Sta. Rpt.* 1898, pp. XXXIX+236).—The report proper contains a list of officers of the station; a financial statement for the fiscal year ended June 30, 1898; a general review of station work by the director; and reports of the heads of the divisions of chemistry, entomology and botany, horticulture, and meteorology, parts of which are noted elsewhere. Reprints of Bulletins 72–79 of the station on the following subjects are appended: Potatoes—Tests with fertilizers (E. S. R., 10, p. 344), experiments for the control of potato scab (E. S. R., 10, p. 363); strawberries (E. S. R., 10, p. 355), the chinch bug (E. S. R., 10, p. 372), earthworms a source of gapes in poultry (E. S. R., 10, p. 393), commercial fertilizers (E. S. R., 10, pp. 336, 734; 11, p. 137), wheat (E. S. R., 10, p. 842), red rust of wheat (E. S. R., 10, p. 864), ginseng—its nature and culture (E. S. R., 10, p. 958).

The Maine Experiment Station, C. D. WOODS (*Maine Sta. Bul.* 62, pp. 45–74).—This bulletin contains a brief historical and descriptive account of the station from its establishment in 1885, a summary of the more important experimental work undertaken, and lists of the subjects treated in the 15 annual reports and 61 bulletins issued by the station since its organization.

Twelfth Annual Report of West Virginia Station, 1899 (*West Virginia Sta. Rpt.* 1899, pp. 45).—A financial statement is given for the fiscal year ended June 30, 1899. A report of the director gives a general review of station work during the year and reports of the agriculturist and chemist review in greater detail the work of their respective departments. Reports of the entomologist and horticulturist are noted elsewhere.

A half century of agricultural experiments at Rothamsted, A. RONNA (*Ann. Sci. Agron.*, 1900, II, No. 1, pp. 139–160).

The work of the society for agricultural education, W. J. BEAL (*Science*, n. ser., 12 (1900), No. 296, pp. 328–334).—This is the president's address at the twenty-first meeting of the Society for the Promotion of Agricultural Science.

NOTES.

ALABAMA CANEBRAKE STATION.—W. Munford, of Uniontown, Ala., has been appointed a member of the board of control in place of S. H. Knight, deceased. The station has begun to print short articles in local newspapers. Experiments have been started for the purpose of getting a grass for winter pasturage.

COLORADO STATION.—F. M. Rolfs has been appointed assistant horticulturist to succeed Carl H. Potter. A. H. Danielson, B. S., of Wyoming, has been appointed assistant agriculturist and photographer of the station and A. F. Lindon, B. S., foreman of the farm.

CONNECTICUT STATE STATION.—George F. Campbell has resigned his position as chemist of the station and M. C. Williams has been appointed in his place.

NORTH DAKOTA COLLEGE AND STATION.—The large barn of the college and station was destroyed by fire January 4, resulting in the loss of considerable important data relating to feeding experiments. Feeding experiments will necessarily be suspended until a new barn can be erected. The barn and contents were insured.

OKLAHOMA COLLEGE AND STATION.—The vacancy caused by the resignation of J. G. Kerr, assistant in agriculture in the college and station, has been filled by the appointment of J. S. Malone, B. S., a graduate of this college.

SOUTH CAROLINA STATION.—A cottage for the station foreman has been completed. A two-story barn, 28 by 50 ft., and a building for fertilizers, with stalls for experiments with pigs underneath, have also been completed. A chemical investigation of rice, its products and by-products, has been partly completed, and the results will soon be issued in bulletin form.

TEXAS COLLEGE AND STATION.—E. A. White, recently connected with the Baron de Hirsch School at Woodbine, N. J., has succeeded A. M. Ferguson as assistant in horticulture at the college and station.

MISCELLANEOUS.—A recent report of the Somerset County (England) Education Committee, as noted in *Nature*, records the presentation by Lord Portman of an experimental farm 5 miles from Taunton, consisting of 142 acres, 80 of which are in pasture. The donor has made considerable alterations and additions to the farm buildings to adapt them to the requirements of the county committee. The primary object of the farm will be experiments on the profitable feeding of farm animals of different kinds, and incidentally experiments will be made on the improvement of land and the best method of growing various field crops.

In a review in *Nature* of the last report of the Woburn Experimental Fruit Farm, Dr. Maxwell Masters suggested the advantage of conducting such a series of experiments on poor soils also, so as to afford a basis for comparison. Following this suggestion, a control station has, according to *Nature*, been established on a relatively barren soil.

The first number has just been received of the new *Journal of Hygiene*, edited by Dr. George H. F. Nuttall, lecturer in bacteriology and preventive medicine in the University of Cambridge, England. It contains, among others, papers on Pathogenic microbes in milk, The red color of salted meat, Artificial modification of toxins, with special reference to immunity, and Studies in relation to malaria. The journal will appear quarterly and will be devoted mainly to original contributions.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The EDITOR and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH.

With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

EXPERIMENT STATION RECORD.

VOL. XII.

No. 7.

The proceedings of the American Veterinary Medical Association for 1900, recently issued, contains a paper on the work of the veterinary section of the experiment stations, by Dr. John J. Repp, of the Iowa Station. This article is worthy of the thoughtful attention of those interested in the development or proper direction of the veterinary feature of experiment station work.

Dr. Repp has taken a census of the opinion of station veterinarians as to their true functions, the work which it is of most importance for them to do, and the general conditions pertaining to their departments. He finds the conditions far from satisfactory, or such as could reasonably be expected to materially advance the cause of veterinary science in very many instances. Only one station veterinarian has no other duties than station work, and in only two cases are the other duties light. In all other cases the burden of the work done is in some other line than that of station veterinarian. Most of the men are reported as being so loaded down with other work that they have very little time for station work. It should perhaps be remembered that thus far veterinarians have been employed by a number of institutions primarily to give instruction in veterinary medicine, and their station duties have been made distinctly a secondary matter, because of lack of funds to equip and run a department of veterinary research. As a matter of fact, however, at fully half the stations where veterinarians are employed as anything more than consulting experts they receive one-half their salary or more from station funds, and in a number of cases three-fourths. Lack of time for investigation or inability to utilize advantageously the fragments of time left from college duties is, unfortunately, not confined to the veterinarians, but is far too prevalent for the best interests of investigation.

Dr. Repp considers separately the various taxes upon the time of the station veterinarian aside from his research work. Of these the most onerous and difficult to avoid are prescribing treatment for sick or diseased animals on the basis of correspondence or otherwise, and examination of pathological and bacteriological specimens for the purpose of diagnosis. Under a strict construction such work is very properly held to be without the scope of the station veterinarian, at

least when it is of such a character or reaches such proportions as to be a hindrance to the real work of investigation. This touches a question of policy which affects nearly every department of the station. It is a difficult matter to make a general decision affecting all work of this kind, but it should be kept well within bounds, and there is perhaps reason why it should especially be restricted in the veterinary department.

The station veterinarian is not employed as a doctor, but as an investigator. He can not undertake to give up his time to public doctoring, any more than the station chemist can to being a public analyst. Both would soon be swamped with mere routine work that would more than absorb their entire time if this practice were encouraged. The station is maintained for the greatest good of the greatest number. No station veterinarian can, even if he devotes all the time and facilities of his department to that one end, doctor or prescribe for all the animals which sicken on the farmers' hands; but one farmer has just as much claim upon him for this service as another. As a matter of fact veterinary science or practice is not materially advanced by this general practice; no progress is made, as the same ground is likely to be gone over year after year, and the greatest good of the greatest number of stock owners is not subserved. Such work is not only unsatisfactory, but even risky for both the advisor and advised, for the descriptions of diseases which are sent in are often such as to make a diagnosis questionable; and furthermore, the station veterinarian, if he is a skillful investigator, may not necessarily be a good practitioner.

In States where a veterinarian is employed as a State officer, we do not find him spending his time prescribing for sick animals which are affected with ordinary ailments. He leaves that to the local veterinarians, while he attends to the larger problems of protecting the health of the live stock at large, restricting epidemics and removing the causes of contagion.

The field of activity of the station veterinarian is even more restricted than that of the State officer, and while a little advice now and then can be given without much trouble, as a rule farmers should be encouraged to employ private practitioners for their animals when occasion calls for their services. We can not agree with the position taken by Dr. Repp that the station veterinarian should render the service as a private individual and then demand a fee for it, when the requests come to him by virtue of his connection with the station. Such requests are in line with all sorts of inquiries which come to the chemist and the agriculturist and the entomologist, and the attempt to collect fees for the service rendered in such cases would be a dangerous one for a station to follow. Carried out consistently it would do far more to promote dissatisfaction than refusal to comply with the requests. But we agree with him entirely that such duties should not

be imposed upon the veterinarian to a point where, in his own judgment, they are a drag upon his more legitimate work.

Dr. Repp calls attention to the opportunities for cooperation with the veterinarians of the State, which he has found very helpful in his own case. By keeping in close touch with these men the station veterinarian is informed of the conditions about his State and can often take advantage of opportunities which arise for investigation in the field. To a certain extent these practitioners will become the medium through which the station's more technical work reaches and benefits the farmer.

Cooperation between the station veterinarians in different States where similar problems are presented is recognized as both practicable and economical. It is a recognition of the maxim that "two heads are better than one," and will often enable each to bring to satisfactory issue pieces of investigation upon which working alone little, or at best very slow, progress could be made. The more limited the time and facilities of the veterinary department the greater would appear to be the advantage of cooperation with other stations.

And, finally, effort should be made to secure from the State additional appropriation for the veterinary work where the stock interests warrant it. In doing this the stations should steer clear of being loaded down with a lot of routine work supposed to be in the interest of the advancement of the stock interests. This is a danger which has often to be met in securing State legislation for aid in a specific line. If interest is aroused it may take the form of a demand for speedy relief from a specific disease or along a particular line, which will involve the station veterinarian in much administrative or routine work which will not advance the science of treatment of disease. There are a number of instances of this kind which serve to illustrate the disadvantage rather than the aid which has followed such legislation. A small appropriation—only enough, perhaps, to pay the salary of a competent assistant—will often open the way for a more thorough line of investigation and be of more real aid in promoting such work than ten times that amount carrying with it duties of inspection, distribution of antitoxins, virus, etc. The Hatch fund should serve as a nucleus around which funds from the State for developing work in a number of different lines, as suggested by the agricultural interests of the State, should be gathered. And in this connection it should be remembered that veterinary work is of necessity quite expensive if it is to be developed so as to form one of the features of the research work of a station.

NEW BUILDING FOR THE COLLEGE OF AGRICULTURE AT THE UNIVERSITY OF ILLINOIS.

The new agricultural building of the University of Illinois, erected at an expense of \$150,000, is nearing completion. It consists of a main portion 248 ft. in length, from 50 to 100 ft. in depth, and 3 stories in height, with 3 wings, each 45 by 116 ft. and 2 stories in height, connected with each other and with the main portion by corridors, all built around an open court. It is constructed of brick and terra cotta, upon a Bedford stone foundation, and roofed with slate. The entire floor space is a little over 2 acres. All partitions, except those of the

FIG. 5.—New Agricultural Building, University of Illinois.

corridors, are entirely independent of the construction of the building, so that the interior arrangement could be changed, if ever necessary, without interfering with the solidity of the construction. The inner walls are finished by painting directly upon the surface of the brick. The floors are of the so-called slow-burning mill construction, made by laying 2 by 6's face down directly upon the beams, covering these with 2 in. of cinders, and upon this laying the upper floor. The building is unusually well lighted by something over 450 windows.

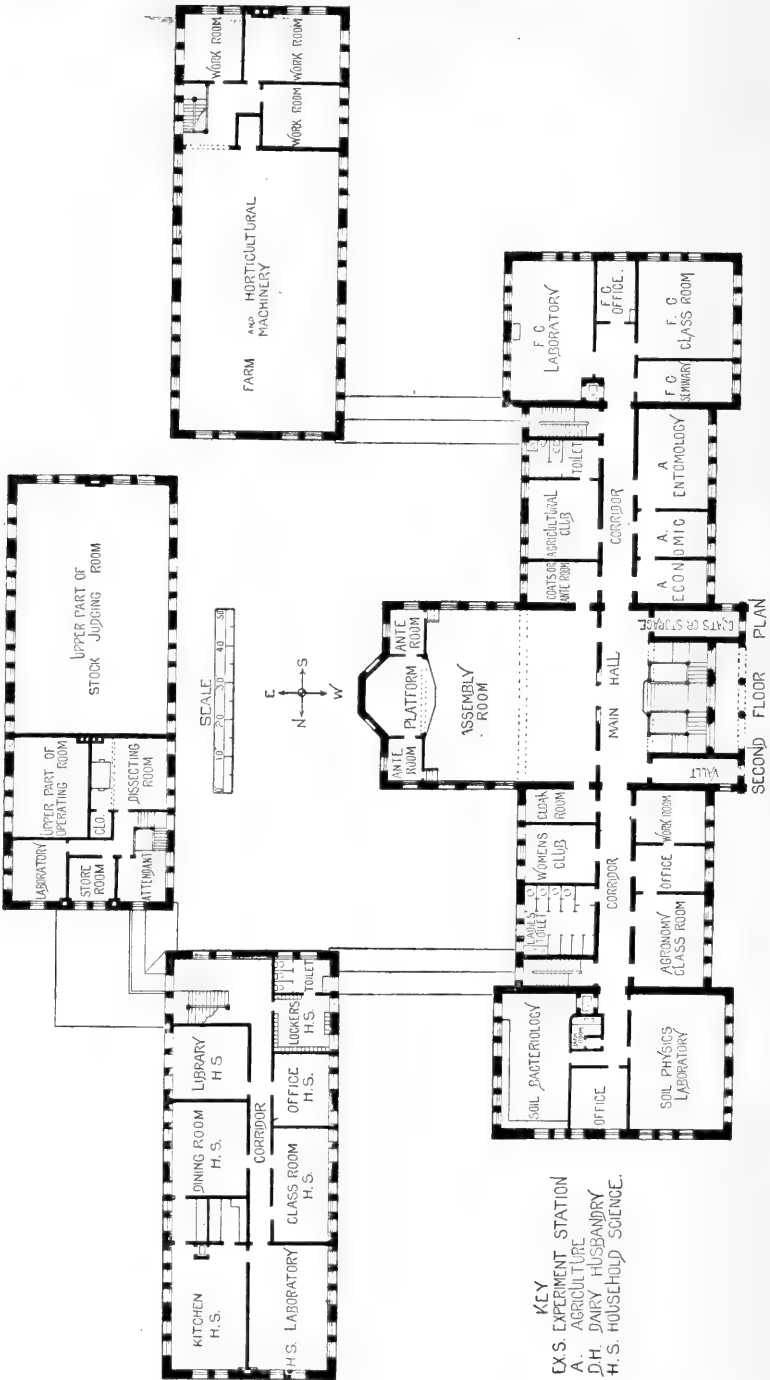

Fig. 7.—Second-floor plan, Illinois Agricultural Building.

The main building (figs. 5 and 6) contains offices, class rooms, laboratories, and seminary rooms, as well as the general offices and the assembly room. The general offices are directly opposite the main entrance of the building, on the lower floor. The entrance is into a lobby 16 ft. square opening into the main office room, 30 by 50, with excellent accommodations for 6 stenographers. Opening off this main room are a stationery room 16 by 20 ft., a fireproof vault somewhat larger, a faculty room, 2 private offices, a storage room, and a mailing room. The space underneath, about 50 by 60 ft., is cemented and will serve as a mailing room for bulletins. The south end of the lower floor is for class rooms and laboratories for horticulture and farm crops, and the north end for animal husbandry and dairy husbandry.

On the second floor of the main building (fig. 7), directly over the general offices and extending to the roof, is an assembly room capable of seating between 400 and 500 people, including gallery accommodations. Upon the south are cloak and retiring rooms for men students

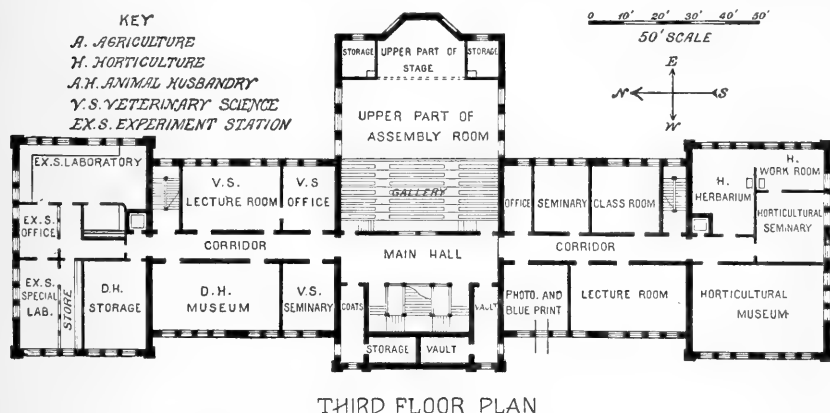

FIG. 8.—Third-floor plan, Illinois Agricultural Building.

and upon the north similar accommodations for women students. It is designed upon occasion, when association meetings are held in the assembly room, that these small rooms may be used by visitors for similar purposes and for committee meetings. The south end of this floor affords further accommodations for work in farm crops, and also a suite of offices for the department of economic entomology. At the north end is located the main office of the department of agronomy, with class rooms adjoining; also the laboratories of soil physics and soil biology. On the third floor (fig. 8) are the experiment station laboratories, vault for the storage of negatives, blue-print room, and the office and class room for veterinary science; also museum for the department of horticulture, etc. The attic is spacious and well lighted and affords excellent storage for lighter materials.

Both floors of the south wing are given up entirely to the subject of farm machinery, and contain two laboratories, each 45 by 70 ft. These laboratories are supplied with line shafting so that any machinery can be set in motion when necessary. This wing is supplied with an office room, class room, and seminary room for students in the subject of farm mechanics.

The east wing contains the stock-judging room, 45 by 70 ft., extending the height of both stories and giving excellent light from above. It is well heated with steam, supplied with a tan-bark floor, and so arranged that animals are fastened in the middle of the room. At the north end of this wing are operating and dissecting rooms for the veterinary department, together with lockers and toilet facilities.

In the north wing the lower floor is devoted to dairy manufacturers, containing bottling and cheese rooms, creamery, wash room, sterilizers, refrigerating plant, and toilet rooms. The second floor is occupied by the department of household science.

The main building is provided with two elevators, and each of the wings with one. The building is heated by steam from the heating plant some 800 ft. away and lighted by electricity from the same source, all pipes and wires reaching the building by a tunnel and being distributed in the subbasement. The interior finish is of yellow pine, excepting in the general offices, which are of oak, and the assembly room, which is of poplar painted white.

At first some doubt was expressed as to the appearance of so large a pile of brick, but capable critics pronounce the building a decided success in every way. This opinion is based not upon any attempt at ornamentation, but upon the general effectiveness of proportions and fitness for the work it is designed to accommodate, and all agree that there is about the building an air of solid dignity that well befits the home of the college of agriculture and the experiment station.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Phosphoric acid in the presence of saturated solutions of calcium bicarbonate, T. SCHLOESING (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 3, pp. 149-153; *Jour. Agr. Prat.*, 1900, II, No. 32, pp. 188-190; *abs. in Bul. Soc. Chim. Paris*, 24 (1900), No. 16-17, pp. 709, 710).—This article reports experiments in which phosphoric acid solutions of known strength were added to a clear saturated solution of calcium bicarbonate, the mixture being agitated by means of a current of air free from carbon dioxid. Free carbon dioxid was gradually evolved, and quantities of the bicarbonate corresponding to the dioxid driven off were decomposed, the phosphoric acid being precipitated in the form of tricalcium phosphate. By gradually increasing the amount of phosphoric acid solution it was possible to precipitate almost the whole of the calcium present, provided the solution was allowed to stand sufficiently long (12 hours). It was shown in these experiments that tricalcium phosphate is very slightly soluble in water free from carbon dioxid. At 16 to 20° C. 1 liter of pure water dissolved 0.74 mg. of phosphoric acid. In 1,200 cc. of water, to which had been added 50 cc. of a saturated solution of carbon dioxid, 6.9 mg. of phosphoric acid was dissolved; in 1,000 cc. of water with 250 cc. of saturated solution of carbon dioxid, 48.5 mg. of phosphoric acid; and in 1,250 cc. of water saturated with carbon dioxid, 91.9 mg. phosphoric acid. It thus appears that the solubility of the phosphate increased with the proportion of carbon dioxid present in the solvent. Tricalcium phosphate is, however, practicably insoluble in carbon dioxid in a saturated solution of calcium bicarbonate. The bearing of this fact on the action of phosphatic fertilizers in the soil and on the formation of natural phosphate deposits is discussed.

A method for the rapid gravimetric estimation of lime, W. H. HESS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 8, pp. 477, 478).—The method proposed is described as follows:

"The lime in the sample is precipitated and separated as the oxalate in the usual way, and the ignition is carried to the point of removing the filter from the residue of lime. The crucible is allowed to cool partially, when a portion of chemically pure dry ammonium nitrate, approximately equal in bulk to the lime in the crucible, and about twice as much chemically pure fused ammonium sulphate are added. A tight-fitting cover is now placed on the platinum crucible and then gentle heat is applied. It has been found very convenient to incline the crucible at an angle of

about 30°, allowing the tip of the crucible cover to project outward and then apply the flame to the tip of the cover, gradually bringing the flame under the crucible as the reaction grows less and less violent. The reaction is complete when fumes of ammonia salts are no longer driven off. Intense ignition is unnecessary and is to be avoided. The crucible should be weighed with its cover."

The weight unit as the basis for calculating results of physical analysis of soils, A. MITSCHERLICH (*Fühling's Landw. Ztg.*, 49 (1900), No. 7, pp. 259-265).—While the results of chemical analysis of soils are usually calculated to the weight basis, it is frequently considered desirable to calculate the results of physical analyses to the volume basis. Two methods of doing this are described: (1) One-tenth liter samples of the air-dried soil which has been put through a 1.5 mm. round-hole sieve and as uniformly compacted as possible are weighed and the moisture determined by drying over concentrated sulphuric acid. From the data thus secured the volume weight is calculated. (2) The specific volume is determined by means of a pycnometer in the usual way, and the water capacity is determined by shaking up the soil (in vessels of known capacity) with water so that the air is completely displaced, the mass being allowed to stand and the excess of water finally removed. The results of these 2 determinations furnish the basis for calculating the volume weight. From the results of tests of these methods on a series of soils the following conclusions are reached: The volume unit is not a safe basis for quantitative physical investigations of the soil unless the specific volume is determined in each case. For quantitative investigations the results may be calculated from a weight to a volume basis with negligible error by assuming an average specific volume of 0.380, adding, in case of humus soils, a correction obtained by multiplying the humus content by 0.003.

Determination of tannin and of gallic acid, F. JEAN (*Rev. Chim. Analyt. et Appl.*, 5 (1900), No. 4, pp. 134-140).—The method is based upon the following principle: When iodine solution is added to a solution of tannin or gallic acid, rendered alkaline with bicarbonate of soda, the iodine forms with the astringent matter a soluble red compound, while starch is not acted upon. Briefly stated, the method is as follows: The total astringent material is first determined by titrating against the iodine solution. The tannin is next precipitated with albumin, and the remaining gallic acid titrated, a correction is made for the albumin solution, and the tannic acid determined by difference. No figures are given showing comparative results with other methods.—H. SNYDER.

Trials of some methods for cellulose determination, C. BECK (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 3 (1900), No. 3, pp. 158-164).—From tests of Lebbin's hydrogen-peroxid method (E. S. R., 8, p. 857) and König's glycerin-sulphuric-acid method (E. S. R., 10, p. 411) in comparison with the Henneberg (Weende) method, the author concludes that Lebbin's method "has neither scientific nor practical

value;" that König's method may perhaps be especially useful in examination of fodders and feces, but that for the comparison of fine-ground feed the Henneberg method is most reliable.

In a reply to the above in the same number (pp. 164-166) König shows that Beck did not follow closely the directions for his method, and points out that the greatest disadvantage of the Henneberg method is encountered with fine grain feed.

No. 6 (pp. 407-411) and No. 8 (p. 539) of the same journal contain controversial articles by Beck and Lebbin on the merits of the latter's method, in the course of which some additional precautions to be observed are pointed out, and Lebbin corrects an error in the original description of his method, 10 volume per cent of hydrogen peroxid being intended instead of 20 per cent.

Purification of phloroglucinol, G. S. FRAPS (*North Carolina Sta. Bul.* 172, p. 69).—The author prepared phloroglucinol by the following method, which gave results in the determination of furfural closely corresponding with those obtained by the use of Merck's phloroglucinol free from diresorcinol:

"About 300 cc. hydrochloric acid 1.06 sp. gr., is heated in a beaker, 11 gm. commercial phloroglucinol added, with stirring, and the heating continued until it has almost all dissolved. Some impurities resist solution, and they may be disregarded. Pour the hot solution into sufficient of the same hydrochloric acid to make the volume 1,500 cc. Let stand at least one night (better several days), to allow the diresorcinol to crystallize out, and filter immediately before using. The solution may turn yellow, but this does not interfere with its usefulness. One hundred cubic centimeters of hydrochloric acid 1.06 sp. gr., dissolves 0.7 gm. of pure phloroglucinol."

Progress in agricultural chemistry, A. HEBBRAND (*Chem. Ztg.*, 24 (1900), Nos. 91, pp. 995-998; 93, pp. 1016-1018).—A brief review of recent investigations relating to soils, fertilizers, and plant and animal production.

The reduction of nitrates by lactic acid, L. VANINO and O. HAUSER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 8, pp. 506, 507).—The authors in their experiments found that the nitrates of the heavy metals were usually reduced by lactic acid, while with the chlorids and sulphates there was little or no reaction. The temperature of reduction was quite different for the different nitrates.—C. B. WILLIAMS.

An improved method for determining the total and permanent hardness of water, C. ACHILLE (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 4, pp. 365-372).

A new method for the determination of aluminum, E. T. ALLEN and V. H. GOTTSCHALK (*Amer. Chem. Jour.*, 24 (1900), No. 4, pp. 292-304).

The influence of temperature on the specific rotation of saccharose, F. G. WIEHMANN (*Ztschr. Ver. Deut. Zuckerind.*, 1900, No. 537, II, pp. 902-936, fig. 1).

The gravimetric determination of solids in milk and the differences resulting from the use of different methods, H. LÜHRIG (*Milch Ztg.*, 29 (1900), No. 24, pp. 371-373). Comparative determinations by different methods are reported and the results are discussed.

Determining butter fat in oleomargarine (*Analyst*, 25 (1900), Dec., pp. 309-313).—The Public Analysts, England, adopted the Reichert-Wollny method for determining mixtures of butter fat and oleomargarine in carrying out the margarin clause of the food and drugs act. A table was adopted for estimating the percentage of butter fat in the mixture.

A comparison of the analytical and calculated results in the estimation of the dry matter in milk, G. AMBÜHL (*Chem. Ztg.*, 24 (1900), No. 81, pp. 871, 872).—The dry substance was calculated by the method of Fleischmann, and compared with analytical results in 116 fresh and 1 and 2 day old samples of milk. In 96.5 per cent of the comparisons, the results differed less than 0.1 per cent. With 48 the calculated results were greater than the determined estimated, in 54 less, while in 14 the results were the same in both cases.

Detection of maize in wheaten flour, G. EMBREY (*Analyst*, 25 (1900), No. 297, pp. 315-317).—A discussion of methods.

Beeswax, J. WERDER (*Chem. Ztg.*, 24 (1900), No. 89, pp. 967, 968).—Studies of methods of analysis and of waxes from various countries.

The determination of free sulphuric acid in wines, F. CARPENTIERI (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 4, pp. 307-340).

The adulteration of coffee with water and borax, E. BERTARELLI (*British Food Jour.*, 2 (1900), No. 21, p. 242).—The author's observations were made on "Santos," one of the inferior grades of coffee sold in Italy. Upon roasting this coffee its weight decreases about 20 per cent; and some manufacturers, to make up this deficiency, soak the berries in water containing borax, the borax being added primarily to harden the coffee grains and prevent the detection of added water.

"Whenever the moisture in roasted coffee exceeds 4 per cent, adulteration may be suspected; and if borax is detected in the sample, the addition of water is certain, as this salt is always added to disguise the addition of water." In examining low-grade coffees one should always be on the alert for adulteration with water and borax.—C. B. WILLIAMS.

Investigation of the Halphen color test as to its value for the detection of cotton-seed oil, R. D. OILAR (*Amer. Chem. Jour.*, 24 (1900), No. 4, pp. 355-373).

The detection of methyl alcohol in mixtures, S. P. MULLIKEN and H. SCUDDER (*Amer. Chem. Jour.*, 24 (1900), No. 5, pp. 444-452).

Progress of starch manufacture, H. HANOW (*Chem. Ztg.*, 24 (1900), No. 82, pp. 889, 890).—Gives statistics and late improvements in the methods of manufacture.

Errors in experiments with calorimetric bomb, LUCIEN (*Ztschr. Angew. Chem.*, 1900, No. 36, p. 910).—The error due to the presence of traces of hydrogen in the oxygen used in determining the heat of combustion of fuel is pointed out.

The rapidity of the combustion in the calorimetric bomb, H. THIELE (*Ztschr. Angew. Chem.*, 1900, No. 25, pp. 607-609, figs. 2).—The article has especial reference to determinations of the heat of combustion of fuel.

BOTANY.

Hybrid conference report (*Jour. Roy. Hort. Soc. [London]*, 24 (1900), pp. 348, figs. 124).—Besides an account of the arrangements for the conference, a list of the principal plants exhibited, and accounts of the conferences at Chiswick and Westminster, July 11-12, 1899, the full text is given of the papers presented at the conference. The following is a list of the papers:

Hybrids and cross breeding as a method of scientific investigation, W. Bateson; Fertilization of the genus *Anthurium*, M. de la Devansaye; The hybridizing of monstrosities, H. de Vries; Hybridization and its failures, G. Henslow; Notes on some experiments in hybridizing and cross breeding, C. C. Hurst; Work of the U. S. Department of Agriculture on plant hybridization, H. J. Webber; Structure of certain new hybrids (*Passiflora*, *Albica*, *Ribes*, *Begonia*, etc.), J. H. Wilson; Hybridization viewed from the standpoint of systematic botany, R. A. Rolfe;

Hybridization in the United States, L. H. Bailey; On self-sterility, F. Ludwig; Crossings made at the Natural History Museum of Paris from 1887 to 1897, L. Henry; Can hybrids be obtained by grafting? E. Juan; Observations on some hybrids between *Drosera filiformis* and *D. intermedia*, J. M. Macfarlane; Eucalyptus hybrids in the Mediterranean region, Trabut; On the particular influence of each parent in hybrids, L. Wittmack; Principles of hybridizing holding good in the majority of cases, M. Leichtlin; Breeding suitable food plants, W. M. Hays; On the use of transparent parchment paper boxes for artificial fertilization, H. de Vries; Hybrid Cinerarias, R. I. Linch; Creation of an important variety of *Crocus sativus*, Attempted hybridization of *Dioscorea*, and Notes on a hybrid of *Mirabilis*, P. Chappellier; A few notes on reproduction in hardy plants by means of hybridizing species and crossing varieties, C. Stuart; Fern crossing and hybridizing, C. T. Druery; Hybrid ferns, H. B. May; Hybrids between the common lilac and the lacinated Persian lilac, E. Lemoine; Hybrid clematis, A. G. Jackman; On the crossing of *Anthurium scherzerianum*, Bromeliads obtained by hybridization, and Gloxinias and their artificial fertilization, M. Duval; Notes on Hybrids, T. Meehan; Chrysanthemums, H. Weeks; On the cross fertilization of the fuchsia, J. Lye; and Notes on some hybrids, W. Smythe.

Changes resulting from etiolation, G. ANDRÉ (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 18, pp. 1198-1201; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 4, p. 489).—According to the author, the etiolation of maize and lupines is not identical. In each case the total amount of carbon is reduced by about one-half, while the proportion of nitrogen remains about the same. The amount of asparagin in the lupine is much larger than that of the maize, the latter plant having apparently used up a portion of the asparagin for the production of new albuminoids. Silica in maize is 30 times more abundant in the etiolated plant than in the seed, and 15 times more than in the lupine. The relative amount of lime is the reverse in the 2 plants when etiolated. In the case of maize etiolated plants contain more potassium than the seed, while in the lupine this is not the case. The amount of phosphoric acid is said to be more abundant in etiolated plants than in others.

Some injurious effects produced by fumigation with hydrocyanic-acid gas, W. R. BEATTIE (*Florists' Exchange*, 12 (1900), No. 29, p. 709).—Attention is called to the fact that under certain conditions it is possible to do serious damage to plants when fumigated with hydrocyanic-acid gas. A house devoted to a general collection of plants was fumigated with one-tenth gram of 98 per cent potassium cyanid per cubic foot of space. The gas was allowed to remain in the house for 20 minutes. All the usual precautions were taken, but many of the plants began to show effects of burning after 36 hours. The damage is attributed to a number of causes. The house was new and tighter than the average greenhouse, and, being unshaded, the sun had produced a vigorous growth of the plants, which were easily injured. The effect of the gas was most noticeable on tomato plants, cardoons, grape cuttings, sweet peas, and Kenilworth ivy.

Among the plants not injured were varieties of cabbage, cauliflower, kale, celery, ferns, palms, loquats, and several species of cactus.

In general, it is stated that houses of mixed plants should not be fumigated with hydrocyanic-acid gas. A better way would be to provide a small room, conveniently located, to which the plants to be fumigated could be transferred.

Importance of bacteria to the development of plants, J. STOKLASA (*Böhm. Ztschr. Zuckerind.*, 24 (1900), pp. 222-227; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 4, p. 498).—A large number of experiments were conducted by the author with *Brassica oleracea* grown in vessels containing sterilized loamy sand. In one case the sand remained sterile; in others it was inoculated with mixtures of the following soil bacteria: *Bacillus mycoides*, *B. fluorescens liquefaciens*, *B. proteus vulgaris*, *B. subtilis*, *B. butyricus*, *B. megatherium*, *B. ureæ*, *B. mesentericus vulgatus*, and *B. coli communis*. To the inoculated vessels were added 5 gm. of dextrose. In every case the total weight of the dried plant and seed were greater in the inoculated than in the sterile vessels. From this the author concludes that in the absence of micro-organisms 'vegetation is abnormal and that incompletely developed seed is produced.

Recent investigations on soil inoculation, J. STOKLASA (*Deut. Landw. Presse*, 27 (1900), No. 7, pp. 389-391; *abs. in Ann. Agron.*, 26 (1900), No. 17, pp. 353-355).—The most important point in this report is the isolation by the author of a second germ without which *Bacillus megatherium* is unable to fix atmospheric nitrogen. This new organism was isolated from humus soils, and the author attributes many of the failures with Alinit to its absence from the soil. The author recommends important changes in the method of applying Alinit. It is advised that 2 gm. of Alinit be mixed with 6 kg. of molasses and 10 liters of water. With this mixture 100 kg. of soil is moistened, the amount being sufficient for a half acre. This mixture is to be protected from strong light, sown and well harrowed into the soil some little time before seeding. By following the directions outlined, good results are claimed for Alinit when used with a number of crops.

In addition to *B. megatherium*, the ability to aid in the fixation of free nitrogen, as shown in experiments with oats, is said to be possessed by *B. fluorescens liquefaciens*, *B. proteus vulgaris*, *B. butyricus*, *B. mycoides*, and *B. mesentericus vulgatus*.

Plant kingdom, A. ENGLER (*Das Pflanzenreich. Leipzig: W. Englemann, 1900, pp. 45, figs. 10*).—This publication, which is the first of a series to be issued descriptive of all the known species of plants, contains descriptions of the genera and species of Musaceæ by K. Schumann. It is the plan of the editor to publish as frequently as material is prepared similar conspectuses of the different families of plants. In addition to the systematic description, notes are given on the literature, morphology, and anatomy of the plants, and also their geographic distribution.

First annual supplement to the fourth State catalogue of Ohio plants, W. A. KELLERMAN (*Bul. Ohio State Univ.*, 4. ser. (1900), No. 28, pp. 10).—A list is given of plants which have hitherto not been reported in the State catalogue of the plants of Ohio. The distribution of the different species by counties is shown.

Fodder and forage plants exclusive of the grasses, J. G. SMITH (*U. S. Dept. Agr., Division of Agrostology Bul.* 2, ser., pp. 86, pls. 2, figs. 46).—This is a revised and enlarged edition (*E. S. R.*, 8, p. 306). Many of the plants here described were either unknown or have become of increasing importance since the first edition. In the present enumeration 333 species of forage and fodder plants are described, 168 of which belong to the Leguminosæ and 30 to the Salsolaceæ.

Studies on American grasses. A revision of the North American species of Bromus occurring north of Mexico, C. L. SHEAR (*U. S. Dept. Agr., Division of Agrostology Bul.* 23, pp. 66, figs. 40).—The present paper contains descriptions of 64 species and varieties, 45 of which are native and 19 introduced. Of this number the author describes 3 species and 15 varieties as new.

Under a discussion of economic importance, *Bromus pumpellianus*, a native of the northern Rocky Mountain region is said to be very promising and, since it is closely related to *B. inermis*, is adapted to similar conditions of soil and climate. Nearly all of the introduced species are said to show decided weed propensities and are quite troublesome, especially in the Western coast region.

Enumeration of the plants producing caoutchouc and gutta-percha collected in the islands of Sumatra, Borneo, and Java, J. G. BOERLAGE (*Stands Plantentuin, Bul. Inst. Bot. Buitenzorg*, 1900, No. 5, pp. 29).—A list, together with brief notes, is given of 76 species of caoutchouc and gutta-percha bearing plants, representing 20 genera.

Investigations on lenticels, H. DEVAUX (*Ann. Sci. Nat. Bot.*, 8. ser., 12 (1900), Nos. 1-4, pp. 1-240, pls. 6, figs. 7).—A report is given on the occurrence and distribution of lenticels in plants, and special studies on their structure, origin, evolution, physiology, and function. An extensive bibliography completes the publication.

The rôle of laticiferous tissues, L. GAUCHER (*Ann. Sci. Nat. Bot.*, 8. ser., 12 (1900), No. 5-6, pp. 241-260, figs. 9).

The relation between the habitat and form of Cruciferæ, E. STEIGER (*Verhandl. Naturf. Gesell., Basel*, 12 (1900), No. 3, pp. 373-401).

Sugar as an aid to the growth of plants, J. GOLDING (*Jour. Soc. Chem. Ind.*, 19 (1900), pp. 324, 325; abs. in *Jour. Chem. Soc. [London]*, 78 (1900), No. 455, II, p. 617).

Recent investigations on the diastatic functions of plants, L. BRÉAUDAT (*Ann. Hyg. et Med. Colon.*, 1900, No. 2, pp. 203-205).

Notes on carbon assimilation, X. WETTERWALD (*Verhandl. Naturf. Gesell., Basel*, 12 (1900), No. 2, pp. 225-243).

The origin of tannin in galls, H. KRAEMER (*Science*, n. ser., 12 (1900), No. 303, pp. 583, 584).—Notes are given on the origin of tannin in galls produced on *Quercus coccinea* and *Q. imbricaria*. If examined in a young state, while the larvæ, which are supposed to be those of *Cynips aciculata*, are immature, a large amount of starch is observed. When the winged insects are developed, specimens treated with copper acetate solutions showed numerous brownish-red tannin masses adhering to the yellowish-brown crystals of gallic acid. The gallic acid appears to be formed at the expense of the starch in the gall, during the chrysalis stage of the insect.

A mold isolated from tan-bark liquors, KATHARINE L. GOLDEN (*Science*, n. ser., 12 (1900), No. 303, p. 582).—A note is given on a bright pink mold isolated from tan-bark liquors which were obtained from a tanning factory employing the liming process. The mold has a characteristic powdery appearance, due to the great number of spores formed. The organism fermented sucrose, dextrose, and maltose. Three distinct enzymes were developed by the action of the mold—a tryptic, a diastatic, and a rennet enzyme—all of which were fairly active.

ZOOLOGY.

The crows of Germany in their relation to agriculture and forestry, RÖRIG (*Arb. K. Gesundheitsamte, Biol. Abt., 1 (1900), No. 3, pp. 235-400+1-151*).—During the progress of the investigations here reported the author examined the stomach contents of 5,148 crows which were killed during 1896 to 1899. Of this number, 3,259 were *Corvus corone* and *C. cornix*, while 1,523 were *C. frugilegus*. Tables are given showing the weight and percentage of the various elements of food found in each of the 3 species; and 151 pages of tabulated material is presented showing the total results of examination of stomach contents. Wheat constituted 5.7 per cent of the total food; rye, 5.5 per cent; oats, 4.7 per cent, and barley 8.2 per cent. Various fruits and garden vegetables, in a greater or less quantity, were found in the stomach contents.

Experiments showed that crows which were fed upon an exclusively vegetable diet died within a short time, and that, therefore, animal food was absolutely necessary for these birds. The animal food eaten by crows included mice, insects, fish, rabbits, pheasants, small birds, and birds' eggs. Vegetable substances constituted 70 per cent of the total food, and animal substances 30 per cent. The insects and other animals which were destroyed by the crows were for the most part injurious to agriculture or forestry, and hence the author considers the crows to be beneficial birds.

The above results are for the two first-mentioned species. In considering the seed crow it was found that plant substance constituted about one-half the food, and animal material one-fourth, while the remainder consisted of gravel and mineral substances. The animal food included mice, insects, meat, frogs, snails, and earthworms.

The author discusses various methods which have been adopted for preventing damages from these birds, including the treatment of seeds with various substances supposed to be distasteful to the crow. Experiments were made with asafetida, quassia bark, and kerosene. These substances did not affect to any great extent the germinating power of the seeds, but did not prevent the crows from eating the seeds.

Legislation for the protection of birds other than game birds, T. S. PALMER (*U. S. Dept. Agr., Division of Biological Survey Bul. 12, pp. 94, pls. 2, figs. 8*).—The author discusses the desirability on general principles of protecting birds which can not be considered game birds, gives a brief history of the progress of protective legislation in the different States, and considers the various definitions of game birds in these State laws. A special account is given of several birds which the author believes have been erroneously considered game birds in such enactments. These birds include pigeons, doves,

flickers, bobolinks, meadow larks, blackbirds, and robins. The definition of various classes of birds other than game birds which are protected is in most cases loose and ambiguous. A brief digest is presented of the legislation of various States upon the subject of plume birds. Attention is called to the widespread prejudice against birds of prey, and it is suggested that at least a number of hawks should be protected on account of their known feeding habits. A table is given showing the species of birds protected in each State and in the Canadian Provinces. A digest is also presented of the regulations regarding the permits for collecting birds and eggs for scientific purposes in different States. The author discusses the Hoar Bill, the Teller Bill, and the Lacey Act.

Appended to the bulletin is a compilation of the State laws for the protection of birds and the laws of the Canadian Provinces on the same subject.

Protection and importation of birds under act of Congress approved May 25, 1900, JAMES WILSON (*U. S. Dept. Agr., Division of Biological Survey Circ. 29, pp. 6*).—This circular contains a copy of the Lacey Act for the protection of birds and a commentary by the Secretary of Agriculture, explaining the powers and limitations of the Department of Agriculture in this matter and the methods which must be adopted by importers or shippers of animals included in the act.

Directory of State officials and organizations concerned with the protection of birds and game, T. S. PALMER (*U. S. Dept. Agr., Division of Biological Survey Circ. 28, pp. 8*).—This list is printed also in the Yearbook for 1899 (pp. 710-717).

Distribution of the seed crow in Germany, RÖRIG (*Arb. K. Gesundheitsamte, Biol. Abt., 1 (1900), No. 3, pp. 271-284, pls. 2*).—The author made a detailed study of the distribution of *Corvus frugilegus* in the various provinces of Germany. Notes are given on the present position of large colonies of these birds, their nesting habits, and upon the means which have been adopted for destroying the birds. Bounties are offered in a number of localities for seed crows.

Revision of the pocket mice of the genus *Perognathus*, W. H. OSGOOD (*U. S. Dept. Agr., Division of Biological Survey, North American Fauna No. 18, pp. 63, pls. 4, figs. 15*).—This bulletin contains an account of the literature relating to the genus under discussion, and a discussion of the distribution, color and pelages, habits, classification, and new species of this genus. An analytical key is presented for the determination of species and subspecies, all of which are described.

The destruction of mice by means of oats treated with strychnin and sugar, A. SCHNEEBELI (*Ann. Agr. Suisse, 1 (1900), No. 7, pp. 269-275*).—On account of the mildness of two successive winters the fields in the canton of Zürich were badly overrun with mice, and great damage to crops resulted. The usual methods for the destruction of these animals proved insufficient during these successive invasions. Recourse was had to inoculation with the bacillus of mouse typhus and to poisoning by means of oats treated with sugar and strychnin. Satisfactory results were obtained by the latter method, and it was observed that dogs and cats which ate the poisoned mice were not affected.

Oligochaeta, W. MICHAELSEN (*Das Tierreich. Berlin: R. Friedländer & Son, 1900, No. 10, pp. XXIX + 574, figs. 13*).—A general systematic account of the earthworms, with extensive bibliographical references.

Arsenical soap and its supposed preservative action upon the skins of museum specimens, L. VIEIRA (*Ann. Sci. Nat., 6 (1900), pp. 29-32*).—From a quite

extensive experience with mounted specimens of birds and animals in museums the author concludes that the use of arsenical soaps upon such specimens has no influence in preventing the attacks of museum pests upon the specimens. *Anthrenus varius* was found to deposit its eggs and multiply as rapidly in skins which had been treated with this soap as in those which had received no treatment.

METEOROLOGY.

Report of the director of the New York Weather Bureau, 1898, E. A. FUERTES (*Rpt. New York State Dept. Agr., 6 (1898), II, pp. 1-473, charts 28*).—This report includes daily and monthly summaries of observations on temperature at some 96 stations in 51 counties of the State, on precipitation at 120 stations, and on atmospheric pressure at 8 stations, a review of the crop conditions during the year, and descriptions and brief historical accounts of some of the stations of the bureau.

The average temperature for the State during 1898 was 48.1° F.; the highest was 103°, at Primrose and West Point, July 3; the lowest, —40°, at Elizabethtown, February 3. The average pressure was 30.03 in.; the highest, 30.71 in., at Albany, March 26; lowest, 28.97 in., at Number Four, February 15. The average precipitation was 43.56 in.; the greatest, 69.2 in., at Brentwood; the lowest, 28.8 in., at Ogdensburg. The average snow fall was 62.4 in., ranging from 143 in. at Number Four to 40 to 65 in. in the interior of the State, and 30 to 40 in. on the coast. The number of days on which precipitation amounted to 0.01 in. was 137. The average cloudiness was 54 per cent.

The principal features of the season from October, 1897, to September, 1898, are shown in the following table:

Monthly temperature and precipitation and departures of each from the normal.

Year and month.		Mean temperature.	Departure.	Average precipitation.	Departure.
		°F.	°F.	Inches.	Inches.
1897:					
	October	51.0	+2.8	1.06	—2.45
	November	37.6	+0.6	4.81	+1.51
	December	28.2	+1.0	3.83	+0.94
1898:					
	January	23.5	+1.6	4.32	+0.89
	February	26.3	+2.8	2.96	+0.05
	March	40.0	+9.8	2.22	—0.51
	April	42.8	—1.0	2.92	+0.25
	May	56.3	+0.2	4.33	+0.86
	June	66.8	+1.0	3.06	—0.72
	July	72.2	+2.4	3.12	—1.03
	August	70.0	+2.5	6.00	+2.34
	September	63.8	+3.2	2.96	—0.41

“The average temperature for the year was unusually high, a deficiency obtaining for the month of April only . . . The crop season on the whole was fairly successful.”

Meteorology, W. FREAR and C. W. NORRIS (*Pennsylvania Sta. Rpt. 1899, pp. 257-277, 284-343*).—“The work of the past 2 years has been chiefly a continuation of the preceding years [E. S. R., 9, p. 815], including observations of the kind usually made by the United

States Weather Bureau upon atmospheric phenomena and upon the amount of sunshine." Monthly summaries of observations are given in the body of the report and the detailed record in an appendix. The summaries for 1897 and 1898 are as follows:

Summary of meteorological observations, 1897 and 1898.

	1897.		1898.	
	Whole year.	Growing season (Apr.-Sept.).	Whole year.	Growing season (Apr.-Sept.).
Barometer (inches):				
Mean	30.050.		30.035	
Highest	30.720 (Jan. 31).		30.533 (Mar. 26)	
Lowest	29.340 (Mar. 24)		29.482 (Feb. 15)	
Temperature (°F.):				
Mean	48.9.	61.8	49.9	63.6.
Highest	92 (July 10, Sept. 16).	92.	95 (July 3)	95 (July 3).
Lowest	-5 (Jan. 26)	24.	0 (Jan. 30, Feb. 2, 4).	17 (Apr. 5).
Greatest daily range	40 (Sept. 16)	40.	39 (Dec. 31)	35 (May 9).
Mean daily relative humidity (per cent).	82.	77.6.	81.3	78.
Rainfall (inches):				
Total	43.44	23.62	34.35	18.68.
Greatest monthly	5.69 (July)		6.51 (Oct.)	
Greatest daily	1.32 (Nov. 1)	1.30	2.11 (Oct. 21)	1.21 (Aug. 4).
Number of days on which 0.01 in. or more of rain fell.	138.	74.	137.	65.
Mean percentage of cloudiness	56.10.	47.5.	56.	50.50.
Number of days on which cloudiness averaged 80 per cent or more.	111.	36.	118.	49.
Average hours of sunshine per day.		6 h. 4 m.		
Wind (miles):				
Total movement	18,990		18,735	
Maximum velocity per hour.	34 (Dec. 24)		40 (Dec. 5)	
Greatest daily movement.	390 (Apr. 27)		580	
Last frost in spring		May 8		May 9.
First frost in fall		Sept. 18		Oct. 3.

The principal periods of crop development in the seasons of 1897 and 1898 are stated.

Meteorological observations, J. E. OSTRANDER, A. C. MONAHAN, and C. L. RICE (*Massachusetts Hatch Sta. Met. Buls.* 139, 140, 141, pp. 4 each).—Daily and monthly summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July, August, and September, 1900, with notes on the general characteristics of the weather of those months.

Meteorology, P. BONÂME (*Rap. An. Sta. Agron. [Mauritius], 1898-99*, pp. 1-15).—Observations on temperature, pressure, humidity, and rainfall during 1898 and 1899 are reported. The distribution of the rainfall and other features of the seasons of the two years are discussed.

Meteorological influences on the growth of beets in 1899, L. KUNTZE (*Ztschr. Ver. Deut. Zuckerind.* 1900, No. 529, II, pp. 153-158).—The influence of the season on the growth of sugar beets is briefly discussed.

An electric frost alarm, L. BURING (*Queensland Agr. Jour.*, 7 (1900), No. 4, pp. 346, 347, figs. 2).—This is a description, quoted from *Garden and Field*, of an apparatus constructed by J. Richard, of Paris. The essential feature of the alarm is a metal tube, similar in construction to the one used in a Bourdon pressure gage, filled with amyl alcohol. The motion caused by the expansion or contraction of this tube with the change in temperature is communicated by means of a metal rod to a clock-like apparatus which operates a pointer on a thermometric scale. This apparatus can be set so that at a given temperature an electric current which rings a bell will be started.

WATER—SOILS.

On the movement of water and salt solutions in soils, S. KRAV-KOV (*Jour. Landw.*, 48 (1900), No. 3, pp. 209-222).—The movement of water was studied with diluvial sand (subsoil) in glass tubes 3 meters long and 3.6 cm. in diameter. The downward movement of water was the most rapid, the lateral movement next, and upward capillary movement slowest. The rapidity and height of capillary rise was almost in inverse ratio to the moisture content of the soil, *i. e.*, the drier the soil the more rapid and the higher the rise. The greater the depth of water maintained over the surface of the soil the more rapid the percolation.

In the experiments with salt solutions, tenth-normal, fifth-normal, and normal solutions of potassium and sodium phosphates (K_2HPO_4 , Na_2HPO_4), potassium and ammonium sulphates, sodium nitrate, chlorid, and carbonate were used in glass tubes 50 cm. long and 2 cm. in diameter filled to a height of 45 cm. with soil (421 gm.). The solutions were maintained at a depth of 0.5 cm. over the surface of the soil and the rate of percolation noted. It was found in the experiments with diluvial sand that the salts which are more readily absorbed by soils percolated more rapidly than those which are not absorbed, although the differences were very small. In experiments with loamy sand it was found that the addition of any of the salts lessened the capillary rise of water, the nonabsorbable salts being more active in this respect than the absorbable. Those salts which tended to loosen the soil had the least retarding effect on the movement of water in the soil.

Experiments on the effect of various salts applied in solid form gave generally inconclusive results. It was observed, however, that gypsum and calcium carbonate hastened the capillary rise of water.

Muck experiments, J. D. TOWAR (*Michigan Sta. Bul.* 181, pp. 157-164, figs. 5).—This is an account of experiments during 1898 and 1899 on tenth and twentieth acre plats of swamp or muck land on the station farm to test the effect of different methods of fertilizing, as follows: Applications of leached ashes, 5 tons per acre in 1898; unleached wood ashes, 1 ton per acre; sand, 1 in. thick over the surface in 1898; air-slaked lime, 2 tons per acre in 1898; commercial fertilizer, containing 2.53 per cent of ammonia, 11.24 per cent of available and 0.26 per cent of insoluble phosphoric acid, and 1.61 per cent of potash, 400 lbs. per acre in 1898, 200 lbs. per acre in 1899; a home-mixed fertilizer, having approximately the same composition as the commercial fertilizer, 355.2 lbs. per acre in 1898, 170.6 lbs. per acre in 1899; stable manure, 20 loads per acre in 1898; nitrate of soda, 400 lbs. per acre in 1899; dissolved phosphate rock, 800 lbs. per acre in 1899, and muriate of potash, 400 lbs. per acre in 1899. Three plats received no

fertilizer, and one of these was thoroughly rolled. The nitrate of soda, dissolved phosphate rock, and muriate of potash were used singly and combined by twos.

A variety of field and garden crops were grown. No definite results were obtained the first year, although in every case the fertilizers increased the yield, the barnyard manure giving the best results. The yields on the different plats are tabulated.

“(1) In general, the result of the muck experiments indicate a uniformity in the requirements of the various crops and that stable manure meets those requirements in fuller measure than anything else. It appears that the legumes tried—garden peas and soy beans—are the only exceptions to this rule. . . .

“(2) Air-slaked lime, which in the past has been highly recommended as a treatment for muck land, acted on this even slightly acid muck in opposition to our expectations, for where it was applied at the rate of 2 tons per acre the yield was generally less than where nothing was applied. The yield apparently increased as the quantity applied was enlarged.

“(3) Sand has given contradictory results, though frequently its yield is higher than the adjacent ‘nothing’ plat. These results are in no measure the entire benefit to be derived from this one application, but it is still a problem whether it will pay to apply sand to a muck field at the rate of 140 loads per acre.

“(4) Leached ashes gave results similar to those from sand, and though yet inconclusive, we believe that where this material may be had for a few cents per wagonload and is within 4 or 5 miles it may be applied with profit.

“(5) So far the complete fertilizers do not give results that will warrant their purchase in considerable quantities for muck land.

“(6) Unleached wood ashes gave very satisfactory results, as did also the mixture of phosphate rock and potash salts, indicating the lack of mineral manures and an abundance of nitrogenous manures in this soil.”¹

The reclamation of salt land in Egypt, G. BONAPARTE (*Jour. Khediv. Agr. Soc. and School Agr.*, 2 (1900), No. 4, pp. 170–175, fig. 1).—The origin and composition of alkali, or *sabach*, as it occurs in Egypt, the injuries which it causes to plants, plants which are resistant to alkali, and methods of reclaiming alkali lands (*ard sabach*) are briefly treated. An effective method of removing the excess of salts practiced in Egypt is as follows: Open drains 70 cm. to 1 meter deep are placed at intervals of 50 meters one way and 150 the other, in the latter case alternating with the irrigation laterals. The main canals are 1,000 meters apart. The water is maintained at a depth of 10 cm. over the soil for 6 months. Rice, barnyard grass (*Panicum crus-galli*), and a sedge (*Cyperus laevigatus*), used in making mats, are then usually planted.

The needs and treatment of the Warwick Plain and other sandy soils of Rhode Island, H. J. WHEELER and G. E. ADAMS (*Rhode Island Sta. Bul.* 68, pp. 159–174).—The district known as the Warwick Plain is “essentially embraced within a line extending from Apponaug to Pontiac, then along the Pawtuxet River to its outlet,

¹The results obtained with sugar beets in these experiments have been reported in an earlier bulletin (E. S. R., 12, p. 540).

and thence around the shore to Apponaug." The soils of this district are with few exceptions comparatively level and naturally poor and sandy. They are also frequently acid. An analysis of a sample of the soil collected near Greenwood is reported, which indicates that there is "a great need of most, if not all, of the kinds of plant food which are liable to be lacking in soils." Plat experiments with fertilizers on table beets and muskmelons at 2 places in the Warwick Plain and pot experiments at the station with barley on soil from one of these localities are reported, with a discussion of the needs of the soils and the best means of their improvement. While the soils are deficient in all of the principal elements of plant food, potash is apparently less needed than either phosphoric acid or nitrogen. "Lime is probably needed as plant food, and particularly to overcome the acidity of the soil." Small applications of lime which has been exposed to the air for a long time are recommended, as well as the stocking of the soil with humus by the growing of leguminous plants for green manure.

Examination of water for household and industrial uses, H. BOURSALT (*Recherche des eaux potables et industrielles. Paris, 1900, pp. 200, figs. 16*).

Miscellaneous water analyses (*Oklahoma Sta. Rpt. 1900, pp. 73-75*).—A brief statement of analyses of 18 samples examined mainly with regard to their mineral constituents.

Lower Michigan mineral waters, A. C. LANE (*Water Supply and Irrigation Papers, U. S. Geol. Survey, No. 31, pp. 97, pl. 1, maps 3, figs. 2*).—"A study into the connection between the chemical composition of these mineral waters and their mode of occurrence."

Underground temperatures during a hot wave in South Australia (*Science, n. ser., 12 (1900), No. 309, p. 851*).—Refers to "an interesting case of slow penetration into the ground of the high temperatures of a hot wave" described in a report by Sir Charles Todd on "Rainfall in South Australia and the Northern Territory during 1897."

Analyses of soils, C. F. JURITZ (*Rpt. Senior Analyst, Cape Good Hope, 1899, pp. 41-71, map 1, dgm. 3*).—This is an account of the work on the systematic soil survey of the Cape of Good Hope to the end of 1899. This work has been reported on from time to time and noted in the Record (*E. S. R., 12, p. 122*).

Soil investigations of the Tokay wine regions, B. VON BITTÓ (*Landw. Vers. Stat., 54 (1900), No. 5-6, pp. 337-348*).—This is a brief record (mostly in tabular form) of examinations, mainly with reference to content of calcium carbonate of the soils of this region, undertaken with a view to determining their adaptability to the American grape.

The rational analysis of clays from the agricultural point of view, E. VAN DEN BROECK (*Bul. Soc. Belge Géol., 14 (1900), No. 3, pp. 161-166*).—This is a discussion of the results of analyses of samples of Tertiary clay from the vicinity of Brabant by the hydrofluoric acid method proposed by A. Proost, which, it is claimed, affords a truer index of the fertilizing constituents of the soil available for the use of plants than the ordinary method using hydrochloric acid.

Investigations on the potash in cultivated soils, C. DUSSERRE (*Ann. Agr. Suisse, 1 (1900), No. 2, pp. 66, 67*).—Attention is called to the greater efficiency of the hydrofluoric acid method than of the hydrochloric acid method in determining the reserve potash of the soil, and tests of the relative action of different fertilizers

in rendering the potash and lime of the soil soluble are reported. The most effective agents in rendering soil potash soluble in distilled water were gypsum and sulphate of ammonia. The substances which were most active in rendering the lime soluble were potassium chlorid and ammonium sulphate.

The effect of sand and lime on heavy marsh soils, KLAUSEN (*Landw. Wechuhl. Schleswig-Holstein*, 50 (1900), No. 46, pp. 794-798, figs. 2).—Beans, fall wheat, clover, barley, and oats were grown in pots of (1) heavy marsh soil alone; (2) heavy marsh soil mixed with 15 per cent of sand which contained 3.58 per cent of calcium carbonate found underlying the marsh soil; (3) mixed with 15 per cent of sand free from lime; (4) mixed with marl containing 3.58 per cent of calcium carbonate; (5) mixed with quicklime equivalent to the amount of calcium in (2); and (6) mixed with noncalcareous sand and calcium carbonate equivalent to the amount of carbonate in (2).

Detailed and summarized results are given. They are believed by the author to show that the value of the calcareous sand is due primarily to the lime which it contains. Its modification of the physical character of the soil is of secondary importance. The sand which contained no lime was valueless and in some instances its use resulted in decreased yields. The leguminous plants were more responsive on the limed or marled soils than the cereals. In general it is concluded that the effect of the calcareous sand in ameliorating heavy marsh soils can be secured much more cheaply by the use of marl at the rate of about 6.7 tons per acre.

Cooperative soil test experiments, J. D. TOWAR (*Michigan Sta. Bul.* 181, pp. 147-157).—Cooperative experiments with fertilizers on corn, potatoes, field beans, and sugar beets at 13 different places in Michigan are reported. The soils experimented with are described and the fertilizers applied and the yields obtained in the different experiments are tabulated. While the results in many cases are inconclusive, in a few instances they furnish the basis for some deductions as to the fertilizer requirements of the soils tested.

Examination of mineral specimens (*Oklahoma Sta. Rpt.* 1900, pp. 68-72).—Examinations of 141 samples are briefly reported.

FERTILIZERS.

On the composition of the gas confined in barnyard manure, P. P. DEHÉRAIN and C. DUPONT (*Ann. Agron.*, 36 (1900), No. 6, pp. 273-294).—Observations made on 2 comparatively large heaps of manure are reported. The observations included determinations of the temperature and humidity of the heaps at stated intervals and chemical examination of samples of gas collected from the top, center, and bottom of the heaps during August and September, 1899. In the chemical examination of the gas, determinations of carbon dioxid, oxygen, methane (CH_4) and hydrogen, and other observations were made. The results show that there was generally sufficient carbon dioxid present in the heaps to prevent the dissociation of ammonium carbonate except in the upper portion of uncovered heaps after a heavy rainfall. Aerobic fermentation was always in progress in the upper part of the heaps and extended to the lower layers when the manure was not closely packed. Wetting the heaps reduced this fermentation. Fermentation resulting in the formation of free hydrogen was observed only in cases of closely packed manure and was

often accompanied by the abundant evolution of carbon dioxid. It occurred only in neutral or slightly acid manure and ceased when the manure was moistened with the liquid which drained from the heaps. Since this fermentation is sometimes accompanied by loss of nitrogen in the free state it should be prevented by keeping the manure heaps moistened with liquid manure. Fermentation resulting in the evolution of methane was found to occur in well-packed manure. In such cases the gas resulting from fermentation is composed solely of methane and carbon dioxid and no nitrogen is lost in the free state under such conditions. The abundant evolution of carbon dioxid which accompanies the marsh gas fermentation also prevents dissociation of ammonium carbonate. This desirable fermentation is promoted by keeping the heaps of manure wet with the liquid portion.

Investigations on the action of the phosphoric acid and nitrogen in Leipsic poudrette and in von Krottnaurer's Blankenburg fertilizer, O. BÖTTCHER (*Deut. Landw. Presse*, 27 (1900), No. 77, pp. 953, 954).—The first of these fertilizers is prepared by drying fecal matter with sulphuric acid; the second by treating slaughterhouse refuse, etc., in the same manner. Analyses of samples of the two products and pot experiments to test their fertilizing value are reported. The samples of poudrette examined contained from 4.3 to 5.38 per cent of phosphoric acid, 1.96 to 2.9 per cent being soluble in citrate solution, and 0.42 to 0.69 per cent soluble in water; 4.19 to 5.54 per cent of nitrogen, 2.16 to 2.4 being in form of ammonia; and 3.78 to 5.1 per cent potash. In the 2 samples of the other fertilizer examined the phosphoric acid varied from 6.4 to 8.3 per cent, 0.1 to 0.35 per cent being soluble in citrate solution and 4.4 to 6.2 per cent soluble in water; 5.49 to 6.34 per cent of nitrogen, 0.31 to 0.39 per cent being in the form of ammonia and 0.15 to 0.21 being in form of nitrate. These fertilizers were compared with double superphosphate and nitrate of soda on oats grown in a moderately compact loam soil. As regards the action of the phosphoric acid the 2 fertilizers were but slightly less effective than the double superphosphate, while as regards nitrogen they were scarcely half as effective as nitrate.

The occurrence and composition of lime in Maryland, together with the results of experiments in testing its use in agriculture, H. J. PATTERSON (*Maryland Sta. Bul.* 66, pp. 91-130, maps 2).—This bulletin includes a general discussion of the relation of lime to agriculture; the action of lime on soils; the time and methods of applying lime; methods of determining the need of lime; descriptions of different kinds of lime used in agriculture; the occurrence and composition of lime in Maryland, including analyses of 121 samples of limestone, 2 of oyster shells, 27 of burned lime (stone and oyster shell) 5 of gas lime, and 90 of marl; and accounts of experiments with lime made at the station since 1889.

In 1889, 1890, and 1891, gypsum 370 lbs. per acre, quicklime 2,000 lbs. per acre, and shell marl 8,000 lbs. per acre, were compared on corn and wheat on a well-drained sandy loam soil, "The results show that the sulphate of lime and the quicklime produced marked effects the first year of application, but that the carbonate showed no effect until the second year. In the sum total of the 3 years' crops all of the applications proved to be quite beneficial, and the quicklime produced the greatest increase in yields."

In another series of experiments with corn and wheat carried out during 1890 and 1891, stone lime 2,000 lbs. per acre, oyster-shell lime 2,000 lbs. per acre, ground oyster shells 2,000 lbs. per acre, marl 4,000 lbs. per acre, and gypsum 233 lbs. per acre, were compared on stiff clay naturally inclined to be wet. In all cases the yields were increased by the application, the ground oyster shells being especially effective, and much more so than the marl.

An account is given of a series of experiments begun in 1893 and partly reported in a previous bulletin (E. S. R., 10, p. 633), to test the effect of lime (20 bu. per acre) on a rotation of corn, wheat, and hay. The results up to the close of 1899 are reported. The figures show "that the application of lime to this land was a beneficial and profitable procedure." In a series of experiments begun in 1896 on stiff clay land, inclined to be a little wet, varying amounts of lime (10 to 60 bu. per acre) were compared on the above rotation. The experiments have been partly reported (E. S. R., 10, p. 633). The results for 4 years (1896-1899), show "that small applications of lime have proven to be as efficient at the end of 4 years as the larger applications, and that the relative profits, up to date, are in favor of applying 20 bu. per acre. It is of interest to note that in the hay crop the 10 bu. of lime gave the largest net return."

Since 1896 experiments have been in progress to test the effect of lime in connection with green manure. Stone lime was applied at the rate of 40 bu. per acre, cowpeas were sown, which were turned under for wheat, the wheat was followed by clover, which was cut for hay, and the land planted to corn. The net gain from the wheat, hay, and corn was \$4.97 in case of cowpeas alone and \$5.03 in case of cowpeas and lime. The combination of cowpeas and lime seemed to have a more lasting effect than cowpeas alone.

During 5 years (1895-1899) experiments have been made to test stone lime at the rate of 1,400 lbs. per acre, oyster-shell lime 1,400 lbs., magnesium oxid 1,400 lbs., barium oxid 1,400 lbs., shell marl 13,000 lbs., finely ground oyster shells 2,600 lbs., gypsum 4,125 lbs., gas lime 2,925 lbs., finely ground South Carolina rock 2,925 lbs., and soft-coal ashes 13,000 lbs. per acre. Corn was grown during 4 years, wheat one (1897).

The reported results show that—

“(1) The best yields were obtained with the lime in the form of a carbonate, the finely ground oyster shells standing first and the shell marl standing second. This was further substantiated when the stone lime was applied as a top-dressing and given an opportunity to form carbonate of lime by absorption of carbonic acid from the atmosphere.

“(2) Pure magnesium lime, which is commonly claimed to be poisonous to the soil and crop, gave the highest yield.

“(3) Barium oxid, which is not a plant food, produced very nearly as much increase in the yields as the calcium oxid, and more increase than the sulphate or phosphate of lime. This would seem to indicate that there was some effect produced on the soil rather than that the plants needed lime as a plant food.

“(4) The lime applied so as to slake in the soil produced a slightly better total yield than when first slaked and harrowed in.

“(5) Stone lime and shell lime were of about the same value on the soil.

“(6) Lime with fertilizer was more profitable than fertilizer alone.

“(7) All the applications of lime increased the yields.”

Experiments in denitrification, T. B. WOOD (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1899-1900, pp. 124, 125*).—Experiments on oats with nitrate of soda alone and combined with fresh (long) and well-rotted (short) manure on a heavy and rather wet clay soil in 1898 and on a lighter humus soil resting on bowlder clay in 1899 are briefly reported. The manure was used at rates of 10 and 20 tons per acre. The average yields were greater with nitrate alone than with nitrate and manure, the difference being especially marked in case of the long manure. With nitrate alone there was an increase of grain of $9\frac{1}{2}$ bu. per acre in 1899; with nitrate and long manure there was practically no increase.

Analyses of commercial fertilizers, C. A. GOESSMANN (*Massachusetts Hatch Sta. Bul. 68, pp. 28*).—This bulletin reports analyses of 275 samples of fertilizing materials, including wood ashes, limekiln ashes, leather-scrap ashes, cotton-hull ashes, silicate, muriate, and sulphate of potash, kainit, nitrate of soda, sulphate of ammonia, bone, tankage, apatite, South Carolina rock phosphate, odorless phosphate, castor pomace, stable refuse, cotton waste, and mixed fertilizers.

Analyses of commercial fertilizers, J. HAMILTON and W. FREAR (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 821-974*).—This includes the text of the Pennsylvania fertilizer law, notes on valuation of fertilizers, tabulated analyses and valuations of fertilizers examined during 1899, and a list of fertilizer manufacturers securing licenses for the sale of fertilizers in Pennsylvania in 1899.

Commercial fertilizers, H. J. WHEELER, B. L. HARTWELL, ET AL. (*Rhode Island Sta. Bul. 67, pp. 151-156*).—Analyses and valuations, accompanied by guarantees, of 14 samples of fertilizers are reported, with a schedule of prices used in the valuation of fertilizers and brief notes on the conduct of the fertilizer inspection.

Analyses of commercial fertilizers (*South Carolina Sta. Bul. 54, pp. 13*).—This bulletin includes a table of prices of unmixed fertilizing materials and tabulated analyses and valuations of 154 samples of fertilizers examined during the season of 1899-1900.

Analyses of fertilizing materials, P. BONAME (*Rap. An. Sta. Agron. [Mauritius], 1898-99, pp. 18-20*).—Analyses of ashes of bagasse and dry cane leaves, calcareous sea sand, and lime used for agricultural purposes are reported.

The rational use of chemical fertilizers, P. LIECHTI (*Ann. Agr. Suisse*, 1 (1900), No. 7, pp. 243-268, figs. 4).—The extent of the use of fertilizers in the Canton of Berne is discussed and an account is given of pot experiments by the Wagner method with oats to test the relative efficiency of different fertilizers on soils of different character. Analyses of the various soils experimented with and the details of the experiments are given in full, with a discussion of the practical application of the results.

The use of lime upon Pennsylvania soils, W. FREAR (*Pennsylvania Dept. Agr. Bul.* 61, pp. 170, figs. 2, map 1).—This is a detailed discussion, based upon investigations at the Pennsylvania Station and elsewhere, of the agricultural uses of lime; the limestones of Pennsylvania; the burning, slaking, and quality of different kinds of lime; the functions of lime in plants and soils; the influence of liming upon soils and the relative value of magnesian limestones; and methods of liming. An appendix gives analyses of Pennsylvania limestones compiled from various sources.

Field experiments with night soil near Posen (*Mitt. Dent. Landw. Gesell.*, 15 (1900), No. 37, pp. 225-228).

FIELD CROPS.

Subexperiment farms, W. M. HAYS ET AL. (*Minnesota Sta. Bul.* 68, pp. 557-730, figs. 38, diagrams. 24).—Results are here recorded of experiments conducted at the 3 subexperiment farms in the State, preceded in each instance by general notes on the purpose of the farm and its method of management by W. M. Liggett.

Experiments at Coteau farm (pp. 563-651).—This farm is located in southwest Minnesota, where droughts are frequent and often severe. The work of the farm has therefore been mainly directed toward ameliorating their effects by different systems of tillage, manuring and cropping, the use of shelter belts, etc.

In a study of the amount of soil moisture best suited to the growth of flax in upland soil containing 13.02 per cent of organic matter and in lowland soil containing 28.6 per cent, the best result in the case of the upland soil was obtained when 30 per cent of water was used. With lowland soil 100 per cent of water gave the strongest flax. These results are believed to show that the larger the amount of organic matter in the soil the greater the endurance of plants to extremes of drought and rainfall.

The results obtained in farm tillage experiments are reported in crop yields and soil moisture content and shown by tables and a comprehensive system of charts. The moisture content of the upper 2 ft. of a soil which had been in wheat and yielded about 2 tons of grain and straw per acre averaged about 15 per cent less than a cultivated soil which had borne no crop. Using 80 lbs. as the average weight of the soil, it is estimated that for each pound of dry matter produced in this case some 261 lbs. of water was required.

The losses of moisture in a field of corn occasioned by the growth of 3,540 lbs. of weeds per acre was very marked, especially at depths of from 3 to 6 in., and the corn crop was reduced from 12,762 lbs.,

where thorough cultivation was given, to 6,989 lbs., or more than 50 per cent, where the weeds (mostly pigeon grass) were allowed to grow freely. It is believed that the weeds evaporated more moisture per pound of dry matter than the corn. This point is being further studied.

Compacting the lower portion of the furrow slices with a subsurface packer has had little or no effect in increasing the moisture in the lower portion of the slices, either when the ground was fall or spring plowed or when coarse manures were plowed under. Subsoiling for corn has apparently reduced the yield of grain 19 per cent and of stover 15 per cent. With wheat the grain yield was slightly reduced and the weight of straw slightly increased on the subsurface-packed plats. Out of 17 comparisons with oats, potatoes, turnips, fodder, corn, wheat, and sugar beets, 14 show a decreased yield from subsoiling. The conclusion reached is that "subsoiling is expensive and not profitable under most conditions in Minnesota."

With wheat the average results for 3 years show equal yields from spring and fall plowing. Practical experience, however, suggests early fall plowing as being more desirable, from the standpoint of economical farm management and weed destruction. A fall-plowed seed bed absorbed more moisture and resulted in an increased yield of 2.6 bu. of grain over an unplowed stubble land. The unplowed stubble seed bed did not conserve moisture as well as the plowed land and more weeds grew on it. Harrowing growing wheat when it is a few inches high has resulted in an average decreased yield for 2 years of 0.6 bu. per acre. In experiments in broadcasting v. drilling wheat, drilled wheat has averaged 9.5 bu. per acre for 2 years and broadcasted 6.25 bu. The drilled wheat was more deeply and strongly rooted and was less injured by frost. Seeding wheat at the rate of about $\frac{1}{2}$ bu. per acre in drills 14 and 21 in. apart and cultivating between the rows has not given as good yields as the usual method of seeding $1\frac{1}{4}$ bu. per acre in drills 7 in. apart without cultivation. Manuring increased the yield of grain and slightly reduced the ratio of grain to straw. It seemed to decrease the moisture content of the plowed ground the first year, while increasing it the second.

The moisture content of soils surface cultivated, mulched, plowed, and plowed and subsoiled was studied. "At the depth of 3 to 6 in. the surface-cultivated soil had only about 1 per cent more moisture during most of the season than the soil which was compact to its surface, and late in the season it had no more." When the soil was plowed 6 in. deep and subsoiled 7 in. deeper, the moisture in the subsoil was much better conserved by the loosened earth than in bare compact soil. Plats mulched with a layer of straw 4 in. deep contained 5 per cent more moisture than bare soil, fluctuated with weather changes less sharply, and retained their warmth longer.

The author briefly summarizes the results of the tillage experiments for the conservation of moisture as follows:

"Soil moisture is conserved by plowing, which loosens the soil to the depth of several inches; by cultivating between the rows, which keeps loose the upper 2 in. of soil; by mulching, which allows the rain to penetrate the soil but not leave it; and by having the plowed furrow slice cleanly fallow all or part of the year, thus avoiding the draft of growing plants on the soil moisture. It is dissipated by growing crops which pump into the air enormous amounts of water; by weeds which are perniciously active pumps in proportion to the useless growth they make, and by leaving the soil compact, allowing capillary water to rise to the surface, there to evaporate."

Among the meadow and pasture crops grown, *Bromus inermis* is the only new grass whose merits have been proven. The yields obtained from 30 mixtures of pasture plants are tabulated, and several mixtures especially adapted to different soils and for different purposes are recommended.

The number of days of pasture furnished by several annual pasture crops for steers and sheep are also shown. The practice of growing succulent forage crops for feeding off during the dry midsummer and early spring and late fall is commended.

The value of the shelter belts of willow hedge at the farm as an aid in growing crops and establishing deciduous trees is considered and a diagram given of the arrangement of the Coteau farm hedges. A four-year-old willow hedge already stands 15 ft. high.

Northwest experiment farm (pp. 652-687).—The northwest experiment farm is located in the rich lowlands of the Red River Valley on ground typical of that region. Results secured in variety tests with a number of grains, grasses, clovers, and forage crops are recorded, as are also data obtained in seeding grasses and clovers with different nurse crops.

Minnesota No. 103 and Wellman Fife have given the best average yields with wheat; Minnesota No. 190, Early Gothland, and Black Russian, in the order named, with oats, and Golden Queen, Odessa, and French Chevalier with barley. *Bromus inermis* has proven one of the most promising of the grasses tested. With this grass and with mammoth clover, and mixtures of timothy and clover, best results have been obtained when seeded without a nurse crop. Red clover has given the best results when drilled in with barley.

Northeast subexperiment farm (pp. 688-730).—This farm is located in the pine region of northern Minnesota, and is made up of a number of different soil types, namely, poor sandy loam, on which jack or Norway pines grow, light-colored clays, swampy soil of the type called "Muskeg," and various mixtures. The general work and equipment of the farm is noted, and some results obtained in field tests with grains, forage crops, potatoes, vegetables, and orchard and small fruits are recorded. Thus far Blue Stem wheats have yielded from 2 to 3 bu.

more per acre than Fife varieties and have been less affected by rust. The Improved Ligowa oat stands at the head of 23 varieties tested. Six-rowed types have given the best yields of barley, and of these Manshury is much the best. White Canada field peas have yielded the best of the peas grown. With forage plants red and alsike clovers have done better on light soils than the true grasses. *Bromus inermis* has given the best results of the grasses tested on light soil. American Wonder has given the highest average yield of the potatoes grown for 3 years—260.4 bu. per acre. The farm is considered as being very nearly the most northerly point at which apples can be grown. The varieties thus found hardy are Silken Leaf and Christmas; crab apples, Martha and Virginia.

Report of agricultural investigations in Alaska in 1899, C. C. GEORGESON (*U. S. Dept. Agr., Office of Experiment Stations Bul. 82, pp. 55, pls. 17*).—This bulletin deals more especially with the establishment of agricultural experiment stations at Sitka and Kenai, and the growing of cereals, forage plants, flax, and vegetables at these stations and at Kadiak.

Experiments in making and storing silage and in making hay from native grasses have been successfully carried out during the year. New lands have been cleared, and the value of lime in correcting the acidity of fresh soil demonstrated. The Alaskan soil is fertile, and when properly drained and treated is productive. All of the common hardy vegetables, such as potatoes, cabbage, cauliflower, kale, peas, onions, carrots, parsnips, parsley, lettuce, celery, radishes, turnips, beets, and the like, of excellent quality, have been grown successfully, and many garden flowers do well. Tomatoes, beans, cucumbers, melons, and sweet corn are not successful. Red, mammoth, alsike, and white clovers grow luxuriantly. They have withstood the winters, and the earlier blooms matured seed. Vetches, lupines, rape, field peas, and timothy have likewise grown vigorously, and yielded a large amount of forage. Wheat, barley, oats, flax, rye, and buckwheat have all matured. Some of the serious drawbacks to grain growing in Alaska are the heavy growth of straw induced by the moist climate and the difficulty of harvesting on account of the abundant fall rains which set in early in September and even in August. Flax grows especially well, producing straw from 2½ to 3 ft. high and of good fiber. Flaxseed has regularly matured.

Notes on the growth of each of a number of varieties of all the above noted crops are recorded in the report and many details given regarding the clearing of land, drainage and improvement of peat lands, Alaska as a stock country, value of silos in Alaska, difficulties in the way of securing homesteads, etc. Letters are reported from a number to whom seeds were distributed giving the results obtained.

Meteorological data showing the temperature and weather conditions in 1899 at a number of different localities are appended.

Notes on clover, J. D. TOWAR (*Michigan Sta. Bul.* 181, pp. 164, 165).—The great difficulty in securing a good catch of clover when seeded with wheat, as was formerly the practice in Michigan, led to experiments in seeding this crop alone on well prepared ground. Two eighth-acre plats 4 rods apart were used in the test. On 1 plat clover was seeded with wheat; on the other the ground was well prepared and the clover seeded alone. Both plats were seeded the same day. The clover seeded with the wheat was an entire failure, though the wheat yielded at the rate of 42 bu. per acre, while on the plat seeded to clover alone a good stand was secured, and a yield of 4.067 lbs. of hay was obtained as a first crop.

Experiments were begun in 1899 to determine the most desirable time to seed clover in Michigan. From results secured up to the present time from April to June seems to be the most satisfactory time for seeding.

Corn experiments, L. FOSTER and L. A. MERRILL (*Utah Sta. Bul.* 66, pp. 101-117, figs. 4).—Different varieties of corn were compared and tests made of the relative value of deep and shallow tillage, of hilling and level tillage, and of thick and thin planting. Earlier results secured along these lines at the station have been noted (E. S. R., 6, p. 527). While corn does not produce as much forage per acre in Utah as alfalfa, it is considered a valuable adjunct to the latter and a desirable crop to grow in rotations, taking the place of an occasional summer fallow in freeing the land from weeds. The climatic conditions for growing corn are not especially favorable in Utah, the seasons being rather too short and the general temperature too low, especially the night temperature. It has been demonstrated, however, that "all of the best flint varieties, the small dents, and the semidents will fully mature in the locality of the experiment station." The dent varieties, however, after being a few years under cultivation tend to take on the appearance of the flints. From 3 to 5 irrigations were given in the different years.

The yield of 17 varieties, including flint, dent, and semident corns, during periods of 5 to 10 years, are tabulated by years and averaged. A white flint corn, the variety usually grown in the Cache Valley, has given the largest yields in 7 out of 10 years, and the highest average by 6.8 bu. of all the varieties tested for 10 years—46.22 bu. per acre. Next in order of productiveness are Angel of Midnight, North Dakota, and Golden Beauty, all flint varieties. The average number of days from planting to cutting corn in Utah has varied with the varieties tested from 116 days in the case of White Flint to 151 days with Long Yellow Flint.

In the deep and shallow tillage experiment, corn was given shallow, medium, deep, and no tillage, and was scarified and mulched with sowed dirt. The test covered 5 years and the results are tabulated for each year. On the whole medium tillage has given slightly the

best results. Two seasons out of 5 the plat not tilled gave better yields than any of the tilled plats, while 4 years out of 5 the plat receiving sowed dirt gave better yields than the plat receiving no tillage.

The experiments in hilling *v.* level culture cover a period of 7 years. Some plats were given level culture or hilled one way while others were given level culture or hilled both ways. The average results are in favor of level culture both ways. For 8 years corn has been planted in hills at the rates of 3, 6, and 9 kernels per hill, respectively. The yield of corn fodder obtained each year is tabulated. The result in favor of planting 6 kernels to the hill was so decisive in the average of the 8 years that the authors feel justified in drawing the conclusion that seeding under or over this amount will not give as good results. Results secured at other stations in tests of hill *v.* drill culture of corn are discussed. In general they "show but very little difference between hill and drill planting."

Corn silage, sugar beets, and mangels—a comparison of their yield and cost of production, H. J. WATERS and E. H. HESS (*Pennsylvania Sta. Rpt. 1899, pp. 104-111*).—Further data on the cost of growing and yield of dry and digestible matter per acre of corn, sugar beets, and mangels are given (E. S. R., 6, p. 446). Three varieties of corn and one each of sugar beets and mangels were grown on an upland clay soil of moderate fertility, uniformly prepared and fertilized. A portion of the corn was grown on unfertilized land and the results included in the general averages with corn. The corn was grown in rows 42 in. apart with the kernels 14 in. distant in the row. When harvested it was hauled to the barn, cut into $\frac{3}{4}$ in. lengths, and ensiled. "The beets were planted in rows 34 in. apart and thinned to one plant every 7 to 10 in. in the row. They were cultivated with a horse hoe 6 times and hand-weeded twice. All vacancies were filled by transplanting." The yield of green and dry matter for each crop is tabulated, and the relative cost of production compared.

The yield of air-dry substance of the mangels averaged 4,554 lbs. per acre, sugar beets 4,683 lbs. per acre, and corn 6,763 lbs. per acre. It is thus seen that the corn yielded about 46.6 per cent more dry matter than the roots. Taking the averages obtained with the corn per acre as a unit, it is calculated that it would require 1.49 acres of mangels or 1.44 acres of sugar beets to produce as much dry matter as one acre of corn.

The cost of the labor and material required to grow, harvest, and store the beets was at the rate of \$57.54 per acre, while the cost of growing and ensiling corn was \$16.17 per acre. "In other words, 4,615 lbs. of air-dry substance in roots cost \$57.56 as compared with 6,763 lbs. of corn at a cost of \$16.17." Or, reduced to a uniform basis, it cost 5.17 times as much to produce 100 lbs. of air-dry substance in the roots as in the corn.

A résumé is given of the cost of growing sugar beets at other stations which shows a variation of from \$33.85 to \$60.50 per acre, with an estimate of \$35 per acre as the lowest average cost under the most favorable conditions; while the cost of growing corn in Illinois has been reported as \$10.59 per acre (E. S. R., 10, p. 540).

Experiments with barley, roots, and grass lands in 1899, H. C. SHERINGHAM ET AL. (*Ann. Rpt. Field Expts. Irish Agr. Organization Soc.*, 1 (1899), pp. 5-43, figs. 6).—Barley was grown in 4 of the more important barley counties of Ireland and fertilized with different commercial fertilizers. Roots were grown in 3 counties, barnyard manure and commercial fertilizers being used, while in 2 others fertilizer experiments were made for the improvement of permanent grass lands. The results secured in the barley experiments show the necessity of early seeding (February or early March). The drills should be 8 in. apart rather than $4\frac{1}{2}$ in. Chevalier barley is advocated for seed. But little advantage was found in sweating barley for seed purposes. It is recommended that phosphatic manures always be applied with nitrate of soda. After a straw crop nitrogenous manures in moderation should be added to superphosphate and potash manures for barley in order to secure a full crop. Nitrogenous manures should never be applied alone.

With the root crops it is shown that heavy dressings of barnyard manure for turnips are not necessary, and that even better crops can be obtained by replacing a portion of the manure with superphosphate. On heavy soils barnyard manure proved of little use, but on porous soils it gave good results, particularly when applied with about 300 to 400 lbs. of superphosphate per acre. The experiments also show that turnips can be successfully produced with commercial fertilizers alone. Phosphoric acid is the ingredient they most require and is best supplied in superphosphate. Kainit on light soils appeared to be a profitable manure when used with superphosphate, but on heavy soils it was injurious. If barnyard manure is not used, nitrogen in the form of nitrate of soda should be applied.

The results on the old pasture lands showed in part that a nitrogenous manure was of but little benefit, while kainit had an injurious effect. Phosphatic manures used alone gave excellent results, while the best results were obtained from a judicious mixture of both nitrogenous and phosphatic manures. Sulphate of ammonia and Peruvian guano are considered the best forms of these manures.

The effect of manures on the percentage composition of the herbage was also studied. The tabulated results show "that the nitrogenous manures produce an injurious effect upon the herbage, reducing the percentage of clover and increasing the percentage of rough, coarse grasses and weeds. On the other hand phosphates and potash, when applied together, and particularly when lime was added to the mix-

ture, largely increased the percentage of clover, reduced the percentage of weeds, and greatly improved the general quality of the hay."

Some hay, forage, and pasture plants for Arkansas, R. L. BENNETT (*Arkansas Sta. Bul. 61, pp. 17*).—The most desirable and satisfactory hay plant for summer growing in Arkansas, considered from the standpoint of food produced and fertilizer added to the soil, is the cowpea, the Whippoorwill and Wonderful varieties being preferred. Detailed directions for growing, handling, and stacking the crop are given, including descriptions of a stack frame for curing hay in unfavorable weather.

As a crop for winter growing for hay, soil protection, and soil improvement, hairy vetch (*Vicia villosa*) has proved most satisfactory, followed in order by crimson clover and red clover. The value of each of these crops in different portions of the State is considered in detail and cultural directions given. Corn and sorghum are considered the best forage crops for the State. Sorghum is preferred for summer feeding for hogs and dairy cows. Cutting may be begun as soon as the stalks begin to head out. Hogs like it best when the stalk is sweet and the grain in the milk stage. In order to preserve the sorghum in this state it is recommended to pile the stalks in large piles and cover with straw. Early amber is the variety usually grown.

The results of 7 years' tests at the station indicate that the grasses best adapted to the soils and climate of the State are orchard grass, Bermuda grass, and hairy vetch for permanent meadows, and Bermuda grass and hairy vetch for permanent pastures. The characteristics of these grasses and the method of cultivation and combining to suit the soils in the different parts of the State are discussed. The prejudice against Bermuda grass held by many farmers, because of its weed-like tendencies, is considered unfounded, since by proper methods of rotation and cultivation the grass is easily controlled. Alfalfa is considered a valuable plant for permanent meadows and pastures where both surface and subsoil are well drained. Considerable care is required in getting it started, but after being once started it is permanent.

A list of the more valuable clovers and other legumes, forage plants, and grasses that have been tested at the station for 10 years is appended. Spanish peanuts and chufas are considered superior to other plants for hogs. Peanuts are considered the better of the two since they yield better and add more fertility to the soil.

Effect of liming upon the relative yields and durability of grass and weeds, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul. 66, pp. 137-146, figs. 11, dgm. 1*).—All the plats used in these experiments have received like amounts of potash and phosphoric acid since 1890. Certain plats have received in addition each year when manure was applied $\frac{1}{3}$, $\frac{2}{3}$, and full rations of nitrate of soda, sulphate of ammonia, and dried blood, respectively; full rations in

each instance representing equal amounts of nitrogen. A definite portion of the southern end of each plat, except the control plat, was limed in 1893 at the rate of $2\frac{1}{2}$ tons of air-slaked lime per acre. The north end of 3 plats received in addition lime at the rate of 5 tons per acre in 1891, and in 1892 an additional amount equivalent to 3.3 tons per acre. Indian corn, oats, clover, and barley were grown on the plats up to the fall of 1897, when they were seeded down with a mixture of 15 lbs. each of meadow-oat grass, awnless brome grass (*Bromus inermis*), Kentucky blue grass, and orchard grass. The Kentucky blue grass failed to germinate. The yield of green material obtained on the limed and unlimed sections of the different plats for each of the years 1897 and 1898 are tabulated. The herbage on definite areas of the limed and unlimed portions of each plat was sorted, weighed, and photographed.

In 1897 the average yield of green material on the limed portions of the plats was at the rate of 6.72 tons per acre, and on the unlimed portions 3.86 tons per acre, a gain of about 74 per cent by liming. In 1898 the average yields on the limed and unlimed sections were at the rate of 5.02 and 1.96 tons per acre, respectively, a gain of 156.1 per cent by liming. Considerable variation in yield occurred on the differently fertilized plats. The largest yield of green material in both years was obtained on the limed plats fertilized with a full ration of nitrate of soda (480 lbs. per acre), followed by full rations of sulphate of ammonia and dried blood. Considerable green material in each instance was grown on the unlimed portions of these plats. In the case of the nitrate of soda plat, this consisted mostly of grass, while with sulphate of ammonia, sorrel was the chief constituent. The especially good showing as regards yields of grass of the unlimed section of the nitrate of soda plats is thought to be due to the gradual neutralization of the soil acidity by years of continuous application of this fertilizer.

As regards the growth of weeds on the different plats, the percentages on the limed section in 1897 ranged from 8.1 to 28.9, though in only one case did it exceed 18.3. On the unlimed sections the percentages ranged from 3.5 to 99.1, and in 3 instances it equaled or exceeded 81.8. The bulk of the weeds on the unlimed section was made up of sorrel.

The weights and percentages of each species of herbage found on the different plats in 1898 is shown in tabular form. With orchard grass and awnless brome grass marked increase in yield regularly resulted from liming. Meadow oat grass was helped some by liming, but was less dependent on its presence than either orchard grass or awnless brome grass. Timothy was not sown on the plats, but appeared in nearly every instance on the limed sections and but twice on the unlimed sections, indicating the value of neutral or slightly

alkaline soil for this plant. Redtop appeared in but 4 instances, 3 of which were upon unlimed soil. This is in accord with previous observations at the station to the effect that redtop can succeed on a soil too acid for the successful growth of either blue grass or timothy. Clover was found upon every one of the limed plats, but was wholly absent on the unlimed sections, and the best clover was found upon the plats which had received potash and phosphoric acid but no nitrogen.

Potato experiments in 1899, G. MARTINET (*Ann. Agr. Suisse*, 1 (1900), No. 2, pp. 45-49, *dgm.* 1).—A record is given of the results obtained in tests of a large number of varieties of potatoes in 12 different localities and of the effect on yield of growing potatoes at different altitudes.

As a result of the tests of varieties, Silesia and Cygnea are recommended for the general crop.

In order to determine the effect of altitude on the yield of potatoes, 2 varieties grown at an elevation of 580 meters were planted at an elevation of 780 meters in comparison with the same varieties regularly grown there. Conversely, tubers grown at the higher altitude were planted at the lower altitude in comparison with the same varieties of native-grown tubers. The results show that the total yields of both varieties were higher by from 5 to 10 per cent at the higher altitude than at the lower, and that the seed tubers from the higher altitudes gave the better yields under all circumstances.

Notes on sand lucern, J. D. TOWAR (*Michigan Sta. Bul.* 181, pp. 165, 166).—Sand lucern was sown on 2 tenth-acre plats on light drifting sand at the station at the rate of 15 lbs. per acre. The lucern was given entire possession of the ground. No crop was produced until the second year, when it was mowed 3 times, yielding at the rate of 6,800 lbs. per acre on one plat and 5,917 lbs. on the other. The plant withstood the severe winter of 1898-99, when fruit trees, wheat, clover, and other hardy plants were killed, and the following season produced 4 crops, amounting to 10,580 lbs. on the better plat. The first cutting was obtained May 31.

Sand lucern is a legume, closely resembling alfalfa. It is recommended for light sandy soils where the moisture is a considerable distance below the surface. Samples of seed have been distributed to the farmers throughout the State for experimental planting.

Sugar-beet and sorghum investigations in 1899, A. D. SELBY (*Ohio Sta. Bul.* 115, pp. 175-193).—*Sugar beets* (pp. 175-188).—The cooperative cultural experiments with sugar beets reported in 1897 and 1898 (*E. S. R.*, 11, p. 142) were continued in 1899. Five hundred lbs. of seed, made up of 4 varieties, was received from this Department and distributed by the station to the farmers throughout the State. An uneven stand was obtained by many farmers. Germination tests

seemed to show that the trouble was not due to poor quality of seed. In order to prevent this loss, earlier planting—in March or early April—is advised. The results obtained in the different sections of the State are tabulated in detail for each grower, summarized, and compared with the results of previous years. The data secured from the northern section of the State were especially satisfactory. The sugar content of 355 samples averaged 13 per cent and the purity 81.5 per cent. For the whole State the averages were 12.7 and 80.2 per cent, respectively.

The striped blister beetle was especially injurious to the sugar beet in many sections of the State during the season.

Sorghum (pp. 189-193).—Five varieties of sorghum seed obtained from this Department were distributed to 122 growers in 54 counties of the State, especially to the central and southern sections. The varieties distributed were chiefly Colman, Folger Early, and Early Amber, with Collier, Oomseana, and Denton in small quantities. The reports are not very definite as to Denton and Collier. Oomseana is highly spoken of, particularly for forage purposes, and some report favorably as to its sirup-making quality. This is a slender, leafy variety, apparently adapted to forage uses. Early Amber has commonly succeeded best for sirup making, because maturing earlier in this State than the Colman, which generally made a larger growth than the other sorts. The Colman receives commendation from some for sirup making and universally as forage for green feeding. Folger Early is reported as standing up better than Colman and ripening earlier than Oomseana.

One of the main objects of the experiment was the distribution of seed to be used by the farmers in the production of seed for future crops. In most instances this result was secured. The detailed report on the growth of sorghum is recorded in letters from 6 farmers, and analyses are given with reference to the sugars found in the sorghum juices and of the composition of 3 samples of sorghum sirups.

The culture and handling of tobacco in Maryland, J. H. PATTERSON (*Maryland Sta. Bul.* 67, pp. 131-152, figs. 8).—Among the topics treated are the methods of selecting, grading, packing, and topping Maryland tobacco; varieties for Maryland and methods of improving them; uses of green manure for supplying humus and improving the yield and quality of tobacco; fertilizers for tobacco; root system of the tobacco plant; methods of tillage; and the relation of original and natural vegetation to the adaptability of soils for tobacco culture.

Trials in growing cigar tobacco at the station have shown that with imported Cuban seed, planted on good soil, a large tobacco of fair quality can be produced. The expense of growing, however, more than counterbalanced the increased price received for the tobacco. The bulk of the crop grown in Maryland is smoking tobacco.

Old tobacco lands at the station which were deficient in organic matter and produced crops with a large proportion of ground leaves were brought into good condition by the use of green manures, supplemented with commercial fertilizers. Crimson clover was the crop used for turning under. It is seeded immediately after the tobacco crop is taken off in the fall, usually the last of August or first week in September, and turned under the following spring in May. By this method of culture the quality of the tobacco has been greatly improved, and within 3 years the yield increased more than threefold. When crimson clover will not do well, cowpeas are advocated. The lack of organic matter in the soil is considered one of the chief causes of the deterioration in quality of the tobacco grown in some sections of the State and the consequent low prices.

In experiments with commercial fertilizers for tobacco, the use of lime and magnesia in large quantities tended to cause a growth that ripened unevenly and was hard to cure, though the combustibility was slightly improved. "On the whole, the application of lime immediately before planting tobacco can not be recommended. Phosphoric acid seemed to have but little bearing upon the combustibility, but generally produced a marked increase in the yield." Potash salts seemed to be the most potent factors in affecting the composition. The use of forms containing considerable amounts of chlorin resulted in tobacco of poor quality and combustibility, while the use of the sulphate and carbonate forms has improved the quality and increased the yield. The following fertilizers are considered as being adapted for use in growing tobacco in Maryland: Dissolved South Carolina rock, dissolved bone, dried fish, bone tankage, cotton-seed meal, nitrate of soda, sulphate of ammonia, high-grade sulphate of potash, carbonate of potash and magnesia, and cotton-hull ashes. These should be used with green manures. The fertilizer used at the station with good results consisted of 1,300 lbs. of dissolved South Carolina rock, 400 lbs. of tankage, 100 lbs. of nitrate of soda, and 200 lbs. of high-grade sulphate of potash. Sulphate of ammonia and nitrate of soda are considered particularly valuable for use in the plant bed for growing strong early plants.

The relationship existing between the vegetation and good tobacco lands, and also the harmful effect on quality of growing certain crops on tobacco lands, is illustrated by a table showing the relative rates at which chlorin and potash are removed from the soil by certain plants common in tobacco sections.

The pine lands (commonly a species of red pine) are considered to be the best tobacco lands in Maryland, and chestnut lands stand next, while "oak and hickory lands are commonly regarded as poor tobacco soil." In the former case the ratio between chlorin and potash removed is comparatively narrow, while in the latter it is very wide.

The much larger amounts of chlorin removed by the pine and chestnut trees suggests a reason for the improved quality of the tobacco grown on such lands. Frequently old fields are allowed to lie idle for a time with the idea of reclaiming them for tobacco. Broom sedge (*Andropogon virginicus*) is one of the most common plants on these fields, and later "old field pines" usually come in. The large relative amounts of chlorin taken up by these plants explains the improvement of such lands for tobacco.

The root system of tobacco at different stages of growth is shown in a number of figures. Frequent and shallow cultivation of tobacco is recommended.

Wheat experiments, J. D. TOWAR (*Michigan Sta. Bul.* 181, pp. 166-169).—These consist of variety and cultural tests and experiments in top-dressing *v.* plowing under manure. In the variety tests 12 different sorts were used. The 3 best sorts in the order of their productiveness were Gold Coin, Dawson Golden Chaff, and International No. 6, all yielding between 31 and 32 bu. per acre.

The cultural experiments with wheat involved 5 different methods of preparing the seed bed. The ground was oat stubble. Plat 1 was gang-plowed 4 in. deep and followed by 2 harrowings and the grain drill; yield, 23.74 bu. per acre. Plat 2 was plowed 8 in. deep, immediately after removing the oat crop, followed promptly by the roller and the harrow, and harrowed thereafter at intervals of about 10 days until the wheat was sown; yield, 23.65 bu. per acre. Plat 3 was allowed to lie until the day before the wheat was sown. It was then plowed, rolled, and harrowed twice with a spring-tooth harrow and once with the Acme; yield, 19 bu. per acre. Plat 4 was harrowed twice with a spring-tooth harrow immediately after the removal of the oat crop. Two weeks later the operation was repeated. It was plowed the day before the wheat was sown as in plat 3, but only one harrowing was found necessary; yield, 22.93 bu. per acre. Plat 5 was treated the same as plat 3, but had been spring plowed for oats instead of fall plowed, as was the case with plat 3. Yield 16.3 bu. per acre. The largest yield was, therefore, from shallow plowing (plat 1), but the author is not convinced that this method of preparation is the best. As a result of this experiment it is concluded that "whatever operations may be performed to conserve the moisture immediately after removing the oat crop will result in an increased yield of the succeeding wheat crop."

The results obtained in top-dressing and plowing under manure were practically identical.

Winter wheat, J. ATKINSON (*Iowa Sta. Bul.* 51, pp. 24-30).—The acreage of winter wheat is being gradually extended in Iowa. The yield obtained from winter wheats has been about double that obtained from spring wheats, the average for 10 years with winter wheats being 45.1 bu. per acre.

Nineteen varieties of winter wheat, chosen because of their supposed hardiness, were grown in 1899-1900. Five of the varieties winter-killed and 10 others partially, while the remaining 4 passed through the winter without the slightest injury. These 4, in the order of productiveness, were Turkish Red, Bearded Fife, Buda Pesth, and Bulgarian. The yields varied from 55.2 in the case of the first to 51.3 with the last. Turkish Red is recommended as the variety best suited to the conditions of the State.

In a test of bald *v.* bearded wheat, the average yield in 1899-1900 for 6 bearded varieties was 47.5 bu. per acre, while for 8 bald varieties the average yield was 17.3 bu.

The milling qualities of the 2 classes of winter wheat, hard and soft, were investigated, samples of 3 varieties of each being submitted to milling experts for their judgment. The average markings were as follows: *Hard wheats*—Turkish Red 99, Buda Pesth 97, and Bulgarian 96; *soft*—Hybrid Prolific 90, Early Ripe 82, and Kentucky Giant 85. It will be noticed that the first 3 wheats mentioned were almost equal in quality to the best spring wheats.

In cultural tests Turkish Red wheat grown after rape yielded at the rate of 59.8 bu. per acre; grown after flax, 58; after buckwheat, 55.3; after millet, 54.7 bu. per acre. Oat stubble was prepared for wheat by plowing under early in August. It was then worked down with a harrow and roller and harrowed once a week thereafter until the wheat was sown in September. Manuring for wheat is not advised. It resulted at the station in considerable lodged grain. From the results of trials in seeding wheat at different dates in September, the author recommends the sowing of wheat as soon after the first week in September as there is moisture enough in the soil to germinate the seed.

When clover or timothy is seeded with wheat, both should be sown in the spring and harrowed in. Fall sowings are liable to winterkill. Seedings of winter oats have uniformly winterkilled at the station, and farmers are advised to plant this crop, if at all, only in very small quantities. United action by farmers in burning over spring-wheat stubble where the Hessian fly is troublesome, followed by deep plowing, is urged as means for the control of this pest.

Diversified farming in Oklahoma, J. FIELDS (*Oklahoma Sta. Rpt. 1900*, pp. 33-44, *figs. 3*).—The chief features of present Oklahoma methods of farming are outlined, suggestions being given regarding the desirability of more diversified farming, and the culture and value of several staple crops for this purpose.

Seed selection, E. GAIN (*Sta. Agron. Nancy Bul. 3, 1900*, pp. 16-25).—A popular consideration of the principles involved, methods to be followed, and the value of seed selection in increasing the yield of farm crops.

The assimilation of matter by two cultivated plants, A. VON SIGMOND (*Jour. Landw.*, 48 (1900), No. 3, pp. 251-264).—Preliminary observations on the increase of dry matter and the taking up of total ash constituents, and nitrogen by maize and tobacco are reported and discussed. The investigations are to be prosecuted further before conclusions are drawn.

Field experiments at Grignon, P. P. DEHÉRAIN (*Ann. Agron.*, 26 (1900), No. 8, pp. 369-383).—Data secured in variety, fertilizer, and irrigation experiments with potatoes, beets, sainfoin, and alfalfa during the unfavorable season of 1899 are recorded.

Field crop tests, H. T. FRENCH (*Idaho Sta. Bul.* 24, pp. 13-18).—Notes and tabulated data on the successful culture at the station of potatoes, millet, and Dwarf Essex rape. Of 134 varieties of potatoes tested, the varieties Cream City, Ford No. 1, Large Puritan, Cambridge Prolific, and Rural New Yorker No. 2, with yields of 384, 356, 349, 342, and 301 bu. per acre, respectively, were the most prolific sorts.

Cost of growing corn, B. W. SNOW (*Amer. Agr. (mid. ed.)*, 65 (1900), Nos. 25, pp. 739, 740; 26, p. 764; 66 (1900), Nos. 1, p. 4; 2, p. 28; 3, p. 52; 4, p. 76).—Statistical data as to the cost of the various cultural operations in growing 4,051 acres of corn in 21 States.

Culture experiments with different varieties of lupines, EDLER (*Landw. Wchnbl. Schleswig-Holstein*, 50 (1900), No. 30, pp. 518-521).—Yellow, black, blue, and white varieties of lupines were grown comparatively on sandy and sandy loam soils. Data as to yields, time of blossoming, alkaloid and albuminoid content of the seeds, etc., are recorded.

Winter oats, M. FISCHER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 19, pp. 718-732, figs. 3; 20, pp. 766-771, figs. 3; 21, pp. 806-810).—The close relation between winter oats and wild oats and the apparent frequent degeneration of the former to the latter forms are discussed.

Seed potatoes from different soils, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt.* 1900, pp. 236, 237, 258).—In this experiment tubers which have been grown in one instance on light soil and in another on heavy soil were used for seed in comparison with home-grown tubers. The yields obtained from the home-grown tubers were on the average 8 per cent higher than those obtained from the imported seed.

Crops of potatoes obtained from sets of different sizes, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt.* 1900, pp. 233-235, 258).—Large, medium, and small whole tubers of 3 different varieties were used for seed. The best results in each case were secured from the medium size potatoes, the increase being 24 per cent heavier than from small seed and 34 per cent heavier than from large seed. No difference in the size of the tubers obtained from planting different size seed was observable.

The effect of planting potatoes at different times, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt.* 1900, pp. 228-232, 258).—Planting potatoes in midseason—about the end of April—has given better average results than planting either earlier or later. The Bruce has been the most satisfactory variety grown.

Sugar plants, L. GESCHWIND (*Ann. Agron.*, 26 (1900), No. 8, pp. 383-409).—A popular consideration of the nature of sugar-producing plants under the following heads: (1) Plants containing sugar, but of little if any industrial importance, such as carrots, melons, agaves, etc.; (2) plants used in the production of sugar on a small scale, like palms, corn, sorghum, and sugar maples; and (3) plants utilized in the manufacture of sugar industrially, *i. e.*, cane and sugar beets.

The sugar-beet industry in New York, C. A. WIETING (*Rpt. New York State Dept. Agr.*, 6 (1899), I, pp. 101-118).—The history of the development of the sugar-beet industry in New York is briefly noted, and an account given of cultural experiments in 1897 and 1898. The sugar-beet factories located at Rome and Binghamton in the State are described.

* **Conservation of beet tops** (*Dent. Landw. Presse*, 27 (1900), No. 89, p. 1088).—Different methods of conserving sugar-beet leaves for fodder, as drying, collecting in heaps and fermenting, feeding green, etc., are considered.

Some experiences with seedling canes in British Guiana, F. J. SCARD (*West Indian Bul.*, 1 (1900), No. 4, pp. 380-386).—A number of promising seedling canes have been grown in comparison with the Bourbon variety. The results obtained have been contradictory.

Tobacco culture, J. C. ESPIN (*Bul. Bot. Dept. Trinidad*, 1900, Oct., pp. 291-304).—This bulletin deals popularly with the culture of tobacco, including harvesting, curing, packing, and baling in Cuba and neighboring islands.

Experiments with grain and the necessity of regularly conducted field-fertilizer experiments, M. FISCHER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 6, pp. 220-229; 7, pp. 248-256).—Fertilizer experiments with wheat after potatoes and with oats are reported, the purpose of which is to show that because of the wide variation in soils and conditions of different localities, each farmer must carry out his own experiments on his farm. Before beginning such an experiment, a definite plan should be outlined. A general scheme is submitted covering fertilizer trials on light and heavy soils. The 3 points covered are (1) determining the fertilizing elements needed; (2) the most profitable amount of fertilizer; and (3) the most suitable form of the fertilizer.

Experiments on wheat at Ghizeh, G. P. FOADEN (*Jour. Khediv. Agr. Soc. and School Agr.*, 2 (1900), No. 4, pp. 160-169).—In variety tests at the station Indian wheats have been found much superior to the ordinary wheat of Egypt. Much better crops have been secured by watering twice, *i. e.*, when the crop is about 14 in. high and just when the flowering stage is reached, than when only 1 watering is given. When the crop is not watered at about the time it is coming into ear, the grain is often small and shriveled in appearance. In the fertilizer experiments the most beneficial results were obtained by the use of nitrate of soda.

Analyses of varieties of wheats (*Ann. Agr. Suisse*, 1 (1900), No. 2, pp. 74, 75).—Analyses, with reference to protein, of 30 varieties of wheat.

Weak straw, J. A. MURRAY (*Ann. Rpt. Field Expts., Univ. Col. Wales*, 1899, pp. 79, 80; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 453, II, p. 498).—Analyses are reported of two lots of rye straw (1) manured with phosphates, nitrogen, and potash, and (2) with phosphates and nitrogen only. The straw in the latter case was too weak to stand, and when dried was so brittle that it could almost be reduced to powder by crushing in the hand. Results indicate that the weakness of the straw was probably due to a deficiency of oil.

HORTICULTURE.

On the limits of the possibility of grafting plants, L. DANIEL (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 3, pp. 192, 193; *Jardin*, 14 (1900), No. 325, pp. 271, 272).—An account is given of 12 unusual unions between plants belonging to different families, obtained by grafting by approach. Successful grafts were made between seedlings of the following plants: Kidney bean and cocklebur, kidney bean and castor-oil bean, sunflower and melon, cabbage and tomato, chrysanthemum and tomato, Jerusalem artichoke and black nightshade, coleus and acaranthus, cineraria and tomato, aster and phlox, coleus and tomato, maple and lilac, zinnia and tomato.

The most perfect grafts in these experiments were made between plants nearest alike in vigor and vegetation. The nature of the tissue of the different plants also played an important rôle. The tomato and

cabbage and the artichoke and nightshade gave good unions on account of their herbaceous nature and rapid growth, while astor and phlox, somewhat advanced in growth, and year-old maple and lilac united with difficulty except on very young shoots.

The success of these experiments leads the author to conclude that the old idea that only plants belonging to the same family can be grafted on each other does not apply to grafting by approach.

Preventing frost injuries by whitening (*Pacific Rural Press*, 60 (1900), No. 18, p. 276).—The text is here given of a paper prepared by J. C. Whitten for the American Pomological Society. The earlier work of the author along this line is reviewed (E. S. R., 9, p. 835), and results secured in 1898–99 added. In order to measure the difference in temperature between the whitened and natural colored buds, fruit twigs of the summer's growth were bored out for about $\frac{1}{4}$ in. of their length and slender thermometers inserted. The twigs were tied so they would all stand vertically and thus receive the sun's rays at the same angle.

"During stormy weather the natural twigs registered a higher temperature than the whitened ones. During very bright sunlight in midday the natural twigs were 15° warmer than the whitened ones. The whitened twigs were nearly of the same temperature as the atmosphere. When the sun came out suddenly bright, however, the whitened twigs did not warm up so rapidly as did the atmosphere. The difference of 15° in temperature explains why whitened twigs do not swell enough to endanger themselves to subsequent injury from cold."

Report on the condition of olive culture in California, A. P. HAYNE (*California Sta. Bul.* 129, pp. 34, pls. 5).—The generally unsatisfactory state of the olive industry in California induced the station to make investigations as to the causes of the depression. Growers and manufacturers in all parts of the State were visited and the culture and commercial status of the olive studied.

The causes of failure in olive culture were found to be improper selection of soil, neglect of tillage, irrigation, proper pruning, and of controlling insect pests. Commercial conditions tending to harm the industry were competition with cotton-seed oil and other oils sold as olive oil, poor harvesting and manufacturing methods, and the selection of unsuitable varieties. Each of these factors is taken up and discussed, and suggestions offered regarding the principles, and, in many instances, the details to be observed in the different operations of successful culture and manufacture. In pruning, care should be taken to have plenty of one-year-old wood on the tree. Vertical branches should be deflected to induce fruiting, and feeble trees renewed by pruning for wood branches. Low pruning is generally advised, except in low, frosty land. The use of about a dozen stands of bees in each 20 acres of orchard at blooming time has proven practical in insuring a good "set" of fruit.

The black scale (*Lecanium oleæ*) with its accompanying fungus, the black smut (*Meliola* sp.), as well as some other scales, were found in olive orchards, most frequently along the coast, in the foggy region. They have been successfully combated by washes, fumigation, and in some instances, by the Australian ladybird. A disease of the fruit, first observed in California in 1897 and since spread all over the State, is noted. It is described as a dry rot, and manifests itself in 3 ways: (1) "It starts at the blossom end and works toward the stem end of the drupe, finally causing it to fall to the ground or dry out on the tree. (2) The decomposition of the flesh cells and the destruction of their contents is first noted at the pit itself, from which point it works outward until it reaches the skin. (3) The decomposition seems to start at the outer surface of the drupe in small isolated spots, from which it works inward until it reaches the pit."

Each of these diseases seems to be restricted to certain varieties. Thus, in the first instance, the varieties Nevadillo Blanco, Rubra, and Pelureur de Grasse are attacked; in the second, Mazanillo, Obliza, and some of the large, fleshy olives; and in the third, the variety Columbella.

The author states that the production of olive oil can not be made profitable unless the grower receives at least 75 cts. per quart for this product. A good demand for large, sound olives for ripe pickles was found to exist all over the State at 75 cts. per gallon, with lower prices for smaller grades. There was a steady market also for standard size green pickles. The author believes olives should be grown for pickles and the small size disposed of to oil makers.

Pickling olives is discussed in considerable detail, as is also the preservation of the product from bacterial growths. The essential factors in pickling are care and skillfulness. The fruit used should be graded for size and color and not be bruised. The latter item was found to be the most general cause of all the failures investigated. The varieties Sevillano, Ascolano, St. Agostino, Cucco, Polymorpha, Macrocarpa, Obliza, and all the very large, fleshy olives are so delicate that they are used almost entirely for green pickles. Large Mission is considered the best variety for ripe pickles for marketing. The value of other varieties for different purposes is noted.

Both pure water and lye processes of extracting the bitterness or tartness of olives are described and formulæ given for salting, etc.

E. W. Hilgard makes the following remarks on the general subject of pickling in conclusion to the bulletin:

"The stronger the lye used in extracting the tartness of the olive the more the flesh is softened and the more difficult it will be to make the pickle keep. Moreover, the stronger the lye, and therefore the shorter the time of extraction, the greater the liability to its being overdone or underdone. It is far better, by repeatedly using a weak lye, say not exceeding 2 oz. per gallon, to prolong the time of extraction and thus to be able to gauge exactly and leisurely the right moment for stopping the process.

I should never expect any fruit extracted within 4 or 5 hours to keep beyond 6 months. As many days will be found to be a wiser economy in the end, the weak lye being removed as often as may be found necessary by its becoming saturated with the 'tartness.' This is easily determined by its ceasing to feel 'soapy' between the fingers. This test is also useful in case an impure 'concentrated lye' has been used.

"The use of salt brine is advisable at any time when the fruit appears to be softening too much, which may readily happen, especially in the case of that which has been grown on low or over-irrigated ground, where it becomes pulpy and large. Such fruit can be firmed, and properly reduced in size, and made to keep by the timely use of brine of properly graduated strength. This use need not be deferred until after the lye has been washed out; the salt in nowise interferes with its action. I consider close attention to this point of extreme importance in respect to the keeping qualities of ripe pickled olives; and it is readily seen that here again the use of good judgment and close observation is of the utmost importance, and that no routine prescription will answer.

"Different varieties of olives must never be treated together. When one is done just right another will be found overdone or underdone. The same consideration applies to fruit of greatly different sizes. No uniformity of texture, flavor, or color can be expected when different varieties and sizes are pickled together."

Small fruits in 1899, G. C. BUTZ and J. F. PILLSBURY (*Pennsylvania Sta. Bul. 51, pp. 6*).—Results are here reported of tests of 61 varieties of strawberries, 39 of which are described, 30 raspberries, 25 blackberries, 12 currants, and 12 gooseberries. Earlier work at the station with the same fruit has been noted (E. S. R., 11, p. 452). The strawberry crop for the season was unsatisfactory, owing to dry weather and consequent small yields.

A comparison was made of the matted row and hill systems of cultivation to determine their relative merits in the production of large-sized berries. The results show that with a little more than one-half of the varieties grown the increase in size of the berries in the hill system of culture over the matted row varied from 0.02 gm. to 4.44 gm. per berry, while with the remainder the increase in favor of the matted row varied from 0.11 to 2.63 gm. per berry.

Summer pinching has been the system of pruning used with raspberries and has proven very satisfactory. All the varieties are kept at a height of 2½ ft. except Shaffer Colossal and Columbian, which are allowed to grow 3½ ft. high.

Liquid dressings applied to strawberries during the fruiting season, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900, pp. 83-92, 251*).—Six different plats, each containing 528 strawberry plants, received liquid dressings during the time the fruit was swelling, as follows: Nothing, water only, and water with either ammonium sulphate, sodium nitrate, potassium nitrate, or ammonium sulphate mixed with sulphate of iron, respectively. The manure applied in the different cases was equivalent to an application of about 15 tons of London city manure per acre. Each plant received about a quart of the different solutions, applied weekly throughout the month,

a quantity equivalent to about 0.1 in. of rain, and therefore possibly not sufficient to insure the proper effect of the nutrients dissolved in it.

"The dressings had a retarding influence on the ripening of the crops, especially with one year plants, owing probably to the period of growth being prolonged thereby. The results with the crops during 4 seasons do not prove decisively the existence of any benefit from such dressings. The 2 plats dressed with nitrates and also that which received iron sulphate show a possible excess of 10 to 34 per cent over the undressed plats, but the differences on which this effect depend are uncertain, inasmuch as they are not greater than those between the 2 sections of the undressed plats."

Manurial experiments with strawberries, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900, pp. 93-97, 251, 252*).—As this experiment has been conducted for only 3 years, it is stated that the results are quoted with considerable reservation. The soil used was light in character. There were 6 plats each made up of 288 plants. One plat received no fertilizer, 2 received 12 and 30 tons, respectively, of London city manure, and the remaining 3 plats a mixture of mineral fertilizers and nitrate of soda in quantities equivalent to the above amounts of London city manure and applied fractionally. The purpose of the test was to ascertain the respective merits of city manures and commercial fertilizers and the effect of altering the amounts applied.

On the whole the different dressings have had but little influence on the crops, the excess obtained from the manured plats for the 3 years being on an average but 5 per cent. One year the yield from the fertilized plats was 11 per cent less than from the nonfertilized, while in 2 other years the increase was 27 and 8 per cent, respectively. The London city manure gave slightly better results on the average than were obtained from the use of commercial fertilizers and slightly higher results, especially the first year, were secured with applications of 30 than with 12 tons. "With artificial manures the indications of the effect of increasing amounts are pretty well balanced in opposite directions in different seasons, the mean result for the 3 years showing a small but insignificant balance in favor of the smaller dressing."

Rubber cultivation for Porto Rico, O. F. COOK (*U. S. Dept. Agr., Division of Botany Circ. 28, pp. 12*).—This circular is a part of a report now in preparation on the useful plants and agricultural possibilities of Porto Rico. Rubber stands third in importance of the commercial products of vegetable origin now imported into the United States, the receipts during 1899 being valued at \$32,500,000. At the present time the largest amounts of rubber are obtained from the tropics of Africa and South America. The extent of the wild supply is unknown, since large portions of these countries have not yet been explored either geographically or botanically. This factor, taken in connection with the possibility that new species will be discovered

which will yield rubber more profitably, the possibility of the discovery of new synthetical methods for producing rubber from turpentine or of methods for extracting a substitute from certain rapid-growing shrubs, as "*Synathereas mexicanas*," the many failures in part or wholly that have attended attempts to build up plantations outside of the natural rubber districts, and the increased cost of using civilized help in the management of tropical plantations, suggests caution in investing large sums of money in the rubber industry. The fact that a species may grow luxuriantly in a new district seems to be no indication whatever that it will profitably produce rubber. Usually the opposite results follow. From 5 to 15 years is given as the probable time required for the growth of rubber trees before they can be tapped for rubber.

The botanical sources of rubber are discussed, and mention made of experiments, generally unsatisfactory, in cultivating Para rubber (*Hevea brasiliensis*), Ceara rubber (*Minihot glaziovii*), and Central American rubber (*Castilleja elastica*) in regions outside of the native habitat of the species. Rubber culture as a feature of mixed farming is thought to be the most rational method to follow in Porto Rico until the possibility of its successful production is more definitely established. Experimental plantings of the most promising rubber trees now known and of new sorts as fast as they are discovered by planters to be carried on in connection with other farming are advocated.

Other factors in rubber production, such as harvesting and coagulating the latex, are touched upon and concluding general notes given on the future of rubber culture.

How to store winter cabbage, A. G. MILLER (*Rural New Yorker*, 59 (1900), No. 2648, p. 718, fig. 1).—Directions are given for building a cellar for storing winter cabbage. Methods of handling the cabbage before being stored are also noted.

Lima bean growing in Ventura County, E. P. HALL (*Pacific Rural Press*, 60 (1900), No. 12, pp. 181, 182).—A discussion of cultural methods in Ventura County, Cal.

Tomato tests on the American Gardening grounds (*Amer. Gard.*, 21 (1900), No. 311, pp. 805, 806).—Of 46 varieties grown during the season, Stone has again been found preeminently the best all-around sort. Trucker Favorite is another good variety. This has a pink skin and is preferred to Beauty, a very similar tomato, but smaller and with a tendency to crack at the base. Other varieties mentioned are Royal Red, Trophy, Early Michigan, and Honor Bright. Enormous is good for exhibition purposes. Golden Jubilee proved by far the best of the yellow varieties tested, and Burpee Cluster the best of the small-fruited or cluster kinds.

Analyses of some edible mushrooms (*Ann. Agr. Suisse*, 1 (1900), No. 2, pp. 73, 74).—Analyses with reference to dry matter and protein are given for 10 species of edible mushrooms.

The effect of pollination, N. KEEP (*Canad. Hort.*, 23 (1900), No. 12, pp. 515-517, figs. 2).—The effect on the fruit of planting Keiffer and Duchess pears in alternate rows is discussed and illustrations given of the cross pollinated fruit. The quality of the Duchess was impaired by cross pollination with Keiffer; but Keiffer was much

improved in quality, color, and especially in form and appearance, by cross pollination with the Duchess.

Grafting with fruit bud twigs, C. TRÉBIGNAUD (*Jardin*, 14 (1900), No. 328, pp. 312-315, figs. 2).—The utility of this method of grafting, conditions on which success depends, method and best time of making the graft, etc., are considered. The author found it valuable in growing the choicer varieties of pears. Vigorous trees which fail to produce fruit may be grafted with fruit buds from other trees in August or September, and fruit obtained on the twigs the following season.

Variety tests of fruit, O. M. MORRIS (*Oklahoma Sta. Rpt.* 1900, pp. 116, 117).—A list of the varieties of apples, pears, cherries, plums, apricots, and peaches that set fruit at the station in 1900.

The pruning of the lemon, C. W. LEFFINGWELL, JR. (*California Cultivator*, 15 (1900), No. 13, pp. 193, 199, 200).—Popular discussion of California methods.

Pruning the lemon tree, R. C. ALLEN (*Pacific Rural Press*, 60 (1900), No. 13, p. 197).—Discussion of principles and methods.

Budding orange trees, W. CARDWICK (*Bul. Bot. Dept. Jamaica, n. ser.*, 7 (1900), No. 11, pp. 169-172, fig. 1).—The preparation of lemon, shaddock, and large sour orange trees for budding, the condition of trees from which sweet orange buds are to be taken, and methods of budding are popularly discussed.

The olive in Algeria, TRABUT (*Bul. Agr. Algérie et Tunisie*, 6 (1900), Nos. 16, pp. 425-472, figs. 32; 17, pp. 481-508, figs. 15).—An historical account is given of olives and varieties in Algeria, with extensive notes on methods of propagation and the manufacture and commerce of olive oil.

Germination of the olive, G. SANI (*Atti R. Accad. Lincei. Cl. Sci. Fis. Mat. e Nat.*, 9 (1900), I, pp. 47-51; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 455, II, p. 613).

Manurial experiments with bush fruits, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt.* 1900, pp. 98-105, 252).—Data are recorded of fertilizer experiments with different amounts of London city manure and certain commercial fertilizers for gooseberries, currants, and raspberries. The results obtained are largely negative owing to the soil being sufficiently supplied with all the different elements of plant food.

Fruit pulp, W. BOULTER (*Ontario Fruit Growers' Assoc. Rpt.* 1899, pp. 116, 117).—The report of a committee appointed to study the desirability of shipping raspberries as pulp into England. If the berries will bring 5 cts. per quart at home it is not advisable to ship abroad as pulp.

Grape growing, O. M. MORRIS (*Oklahoma Sta. Rpt.* 1900, pp. 90-103, figs. 10).—A popular treatise on the propagation, cultivation, pruning, and trellising of grapes. Grapes have proven the most uniformly hardy and productive of the fruits grown in Oklahoma. Moore Early, Concord, and Worden are considered the 3 best black grapes; Delaware and Catawba the best red grapes; and Niagara, Moore Diamond, and Goethe the best white or pink grapes, the varieties under each color being mentioned in the order of earliness. Grapes that are gaining favor are Herbemont, Jaeger Cottage, and Brilliant, while Rommel, Admirable, Early Ohio, Fern Munson, and Green Mountain are other especially promising varieties.

Viticulture in Hérault in 1900 (*Bul. Soc. Cent. Agr. Hérault*, 87 (1900), Jan.-June, *Append.* pp. 90, figs. 25).—A symposium composed of the following papers: Production and consumption of wine in Hérault, J. Leenhardt-Pomier; Vines, L. Ravaz; Cellars, P. Ferronillat; Climatic conditions, F. Houdaille; Geology of the region, H. Lagatu; Composition of the wines, L. Roos; and The historic and economic situation of viticulture, Coste.

American vines and the phylloxera situation in Switzerland, J. DUFOUR (*Ann. Agr. Suisse*, 1 (1900), No. 1, pp. 44, figs. 11).—The nature of the different American grapes used for stocks in districts affected by the phylloxera and methods

of propagating them are described in the first part of this work, while in the second part some results obtained in experiments with different American species and hybrids to determine their relative value on different soils in the Canton de Vaud are recorded.

Chestnut culture, E. B. ENGLE (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 301-312, figs. 10*).—Popular discussion of the culture, propagation, insects, diseases, and varieties of chestnuts. With reference to propagation the author states that "seedlings grown from Paragon nuts grow more vigorously, form a better union, and make a larger percentage of good trees than seedlings grown from native chestnuts."

Cacao industry in Grenada, G. W. SMITH and D. MORRIS (*West Indian Bul., 1 (1900), No. 4, pp. 415-422*).—Suggestions regarding the management of cacao groves and the renovation of old plantations.

Walnut culture in California, J. M. DICKENSON (*California Cultivator, 15 (1900), No. 12, pp. 177, 183, fig. 1*).—Culture and management.

Notes on the Gladiolus, H. H. GROFF (*Amer. Gard., 21 (1900), Nos. 304, p. 698; 310, pp. 792, 793; 312, p. 830; 313, pp. 848, 849*).—The characteristics of different strains and hybrids are discussed.

A summer's work abroad, in school grounds, home grounds, playgrounds, parks, and forests, MIRA L. DOCK (*Pennsylvania Dept. Agr. Bul. 62, pp. 33, pls. 9*).—The author visited England, Edinburgh, and Germany, and spent a few days in Switzerland and Paris. Six public bath houses, 14 school buildings, and 110 parks and playgrounds were visited and a tour made through the Black Forest. The more striking features met with in the journey are recounted and furnish much suggestive matter relative to the management and improvement of Pennsylvania school grounds, public parks, and forests, as well as similar institutions in other States.

FORESTRY.

Miscellaneous notes in botany and forestry, W. A. BUCKHOUT (*Pennsylvania Sta. Rpt. 1899, pp. 245-256, pls. 5, fig. 1, charts 3*).—The writer reports upon the time and rate of formation of the annual ring of wood in the European larch and the white pine. Observations were made during the years 1897, 1898, and 1899. In the case of the larches the growth of wood began during the last week in April, with seasonal differences due to temperature, moisture, etc., although their effect was hardly appreciable. The beginning of wood formation practically coincided with the appearance of new leaves on the larch. Diagrams are given showing the variations in seasonal growth with both species. The absolute growth of the white pine was considerably greater than that of the larch, and the growing season of the pine continued into September while the larch made little or no growth after July. The pine showed greater uniformity in amount of yearly growth, only $\frac{1}{16}$ in. difference occurring during the 3 years in question, while the larch showed a difference amounting to $\frac{3}{16}$ in. It is thought probable that the specimens of larch taken for the experiment were hardly representative, as from their appearance they had probably passed the time of maximum yearly growth. While there have not been sufficient experimental plantings to give definite data, the author believes that the larch, while not as long-lived or producing as great a bulk of wood as the pine, can be advantageously grown for many purposes.

Notes are given on the depreciation of forest trees and results of the failure to cut trees at maturity. Numerous examples are given of depreciation in value attributed to decay, and various signs of decay are pointed out.

The undesirability of red and black oaks, because of fungus diseases, is mentioned. These oaks, particularly the black oak, are specially subject to a disease of the same nature, if not identical, with the canker of the apple tree (*Nectria ditissima*). It is said that few trees incurring this disease overcome or outgrow it and, as a rule, they fail completely before attaining a diameter of 10 in. at the base. The disease is much more common in sprout or coppice growth than in seed-grown trees. A judicious selection should be continually carried on during the early years of forest growth, cutting out the undesirable species and particularly every tree which shows the beginnings of disease. The white oak seems to be entirely free from this disease, while most of the other species are affected to a greater or less degree.

Notes are given on the injury produced on white pine by the pine weevil. It is said that one of the most serious obstacles to the growth of the white pine is the pine-tree weevil (*Pissodes strobi*), a small beetle which lays its eggs in the young terminal shoots and occasionally in the uppermost laterals. The young grubs bore through the bark to the wood, completely destroying the shoots. The ravages of this insect are said to be very common, destroying during the past year the tops of at least 10 per cent of the white pine trees, as well as seriously attacking Norway spruce and other ornamentals.

Notes are given on various shade trees for street planting. The tulip and magnolia on good loamy soils, with plenty of room and good drainage, are said to be well adapted to this purpose. They should not be set closer than 50 ft., and 60 ft. is better. The same conditions apply to the sycamore and elm trees. Maple trees vary considerably with the different varieties. The silver maple gives the quickest results with possibly one exception of any shade tree, but for best growth requires a moist fertile soil. The hard maples are considered among the most desirable for shade trees, succeeding well on a variety of soils, and are believed to be nearly free from insect or fungus attacks. The European species, while generally more rapid in growth during early life, are said to soon reach the limit of growth and never make as large trees as the American species.

The cottonwood and other poplars, on account of their rapid growth, are frequently recommended for street trees, but they do not last as well as some other varieties and become very unsightly with age. The tendency to sprout from the root is also considered objectionable. The objections urged against the cottonwood are said to apply to ailanthus, and in addition this tree has an irregular habit of branching, so that old trees become very unsymmetrical.

Report of the commissioner of forestry, J. T. ROTHROCK (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 123-139*).—Brief accounts are given of forestry operations which have been begun. An attempt has been made to start plantations of Carolina poplars (*Populus deltoides*) for paper manufacture. Attention is called to the value of the chestnut as a source for tanning extracts, and the effect of forest fires in destroying this crop.

The losses by forest fires in Pennsylvania during the year 1898 are mentioned, from which it appears that 22,853 acres were burned over at a loss of \$53,000. The timber cut during the same period was 130,000 acres, including 107,000,000 ft. (b. m.) of white pine, 858,000,000 ft. of hemlock, 416,000,000 ft. of other lumber, and 534,000 cords of bark peeled.

An estimate is made of the timber lands as they now exist in the State, the area being given by counties. From the tabular statement given, it appears that there are 2,765,000 acres of full-grown timber land, 2,944,000 acres of half-grown timber land, and 4,443,000 acres of brush land.

Some cooperative experiments with forest tree seeds, G. C. BUTZ (*Pennsylvania Sta. Rpt. 1899, pp. 227-244*).—A report is given of cooperative experiments begun in the fall of 1896 in connection with the Division of Forestry of this Department. The plan of the experiment was to study the climatic effect upon several widely distributed species of forest tree seedlings. The species chosen for the first year's planting were black walnut, bur oak, hickory, honey locust, box elder, green ash, and white ash. Tabulated data are given showing the results of the different plantings, in which the time of germination, height of tallest seedlings, average rate of growth, effect of spring frost, and date of fall of the leaves of each species are given. Comparisons are noted showing the results of fall and spring planting of seeds. The spring planted seeds were stratified during the winter, and in the case of the walnut, bur oak, box elder, and white ash, the spring planting gave the highest average of germinations.

Forest protection and restoration, T. P. LUKENS (*Forester, 6 (1900), No. 5, pp. 100, 101*).—The forest conditions of southern California are briefly reviewed, and it is urged that means should be taken to repair the injury due to forest fires, overpasturing, etc. In reforesting this region, the author suggests the planting of pine seeds on burned areas as soon as possible, in order that the trees may keep above the brush growth which follows forest fires. Growing at different altitudes, it is said that different species of pines, cedars, spruces, and firs may be found adapted to the conditions found in that region. This reforestation, it is believed, can be done at no great expense, \$20 per acre being the estimated cost of seed and all labor.

Forest influence on water flow, H. S. GRAVES (*Forester, 6 (1900), No. 5, pp. 113, 114*).—A brief report is given of an investigation of the

Mill Creek watershed in Pennsylvania. As a result of this investigation it is stated that a more uniform flow of water can be obtained by proper management, and in addition the forest can eventually be made a source of considerable income. The entire watershed was originally covered with hemlock and mixed hard woods, although at present no considerable area of the virgin forest remains. About four-fifths of the entire tract has grown up in second growth, and one-fifth is or has been recently under cultivation. It is suggested that this region should be replanted, the large open areas with white pine, alternating with fields seeded to black locust, in which oaks and chestnuts should be planted later. Under the system of planting and management suggested it is believed that within 10 or 20 years many of the trees would become of marketable size, so that it would be a source of considerable income to the management.

Tree planting (*Oklahoma Sta. Rpt. 1900*, pp. 118, 119, fig. 1).—The results of the tree-planting operations of the station for the year are briefly reviewed, in which the number of trees planted in February, 1900, and those living June 1 are given. The trees were young seedlings and set in rows 4 ft. apart and from 2 to 4 ft. apart in the row. In all, 35,000 trees of the following varieties were planted: White elm, soft maple, catalpa, black locust, box elder, white ash, and honey locust. The proportion of those dying from varying causes ranged from 2 per cent in the case of the soft maples to 65 per cent in the case of the white ash.

Sowing tree seeds, etc., Pinehurst Nurseries, N. C. (*Amer. Gard.*, 21 (1900), No. 304, pp. 693, 694).—Directions as to time and method of planting a large number of trees and shrubs.

The forests of Indiana, J. P. BROWN (*Forester*, 6 (1900), No. 5, pp. 110-113).—An address in which the past and present conditions of the forest of the State are reviewed. Notes are also given on the rate of growth and durability of a number of species of trees.

Forest conditions in the Klondike (*Sci. Amer. Sup.*, 49 (1900), No. 1267, pp. 20311, 20312).—Popular description of the forests of the interior of Alaska and adjacent regions.

The pine forests of northwestern Germany, ERDMANN (*Allg. Forst u. Jagd Ztg.*, 76 (1900), Jan., pp. 11-22).—Describes the pine forests occurring upon the clay regions of northwestern Germany.

Forest management in Germany, EBERTS (*Allg. Forst u. Jagd Ztg.*, 76 (1900), pp. 50-56, 102-106, 167-170, 197-200).—The systems of forest wardens and management for Hesse, Mecklenburg-Schwerin, Meiningen, Saxony, and Wurttemberg are described.

Some forest problems in northwestern Russia, H. MAYR (*Allg. Forst u. Jagd Ztg.*, 76 (1900), pp. 81-91; 117-131, 156-160).—The forests, their value, and their necessities are described.

Investigations of the more important deciduous trees of Japan, S. KAWAI (*Bul. Col. Agr. Imp. Univ. Tokyo*, 4 (1900), No. 2, pp. 97-152, I-IX, 11-18, pls. 9).—The timber characteristics of a large number of the deciduous trees as shown by cross radial and tangential sections and bark appearance are given.

The genus *Tilia* in Japan, H. SHIRASAWA (*Bul. Col. Agr. Imp. Univ. Tokyo*, 4 (1900), No. 2, pp. 153-165, pls. 2).—The Japanese species of *Tilia* are mentioned and 2 new species described, *T. kiusiana* and *T. maximovicziana*.

The forests of Java and their exploitation, SEIBT (*Allg. Forst u. Jagd Ztg.*, 76 (1900), pp. 160-167, 192-197, 236, 241, 271-279).—The wooded area of the island

is estimated at 126,447 square kilometers. The rainfall and climate are discussed, the forests described, the relative value of the woody species indicated, and methods of management described.

Mixed forests of pine, fir, and larch, REISS (*Allg. Forst u. Jagd Ztg.*, 76 (1900), June, pp. 189-192).—The requirements of each species are described, their value as components of mixed forests mentioned, and methods suggested for securing such mixtures.

On the growth of oak and other deciduous species in beech forests, H. BERTOĞ (*Ztschr. Forst u. Jagdw.*, 32 (1900), No. 4, pp. 188-212, figs. 10).—Notes on the requirements and growth of various species of oak, ash, maple, etc., growing in beech forests.

Comparative ash analyses of red fir and European spruce, E. HOPPE (*Centbl. Gesam. Forstw. Wien*, 26 (1900), No. 2, pp. 49-54).—Comparative ash analyses of *Pseudotsuga douglasii* and European spruce are given.

Physiological investigations on the increase in diameter and the quality of the timber of *Pinus sylvestris*, F. SCHWARZ (*Physiologische Untersuchungen über Dickenwachstum und Holzqualität von Pinus sylvestris*. Berlin: P. Parey, 1899, pp. 371, pls. 9, figs. 5; noted in *Allg. Forst u. Jagd Ztg.*, 76 (1900), Mar., pp. 106-110).

On the estimation of the yield of oak forests, WIMMENAUER (*Allg. Forst u. Jagd Ztg.*, 76 (1900), Jan., pp. 2-9).—Tables are given for estimating the yield of oak forests. The characteristics of the various forests where the tables have been tested are given. *Quercus pendunculata* and *Q. sessiliflora* were the dominant species, with beech, ash, alder, linden, elm, and several conifers forming the secondary growth.

Rapid estimation of the cubic contents of fir trees (*Rev. Eaux et Forêts*, 3. ser., 4 (1900), No. 1, pp. 17-21).—Formulas are given for the estimation of the contents of workable timber in fir trees. It is based upon the rule that the cubic contents of a fir tree 24 meters in height equals 10 times the square of the diameter of the tree at the height of a man.

An international commission on timber physics, SCHWAPPACH (*Ztschr. Forst u. Jagdw.*, 32 (1900), No. 4, pp. 230-233).—An account is given of previous attempts in the formation of such an international commission for securing uniformity of methods.

The influence of forests upon the temperature of the air, MUTTRICH (*Ztschr. Forst u. Jagdw.*, 32 (1900), No. 3, pp. 147-167).—Gives records made at periods of 2 hours daily for 3 years in which the temperature of a forest and an open field are compared.

Pasturing forests, A. MATHEY (*Le pasturage en forêt*. Dijon, 1900; rev. in *Rev. Eaux et Forêts*, 3. ser., 4 (1900), No. 5, pp. 156-158).—The results of the author's personal observations upon the effect of pasturing forests.

Annual review of the literature of forestry, T. LOREY (*Allg. Forst u. Jagd Ztg.*, 76 (1900), Sup., pp. 1-98).—Briefly reviews the forest literature relating to forest botany, zoology, etc.

DISEASES OF PLANTS.

The fungus infestation of agricultural soils in the United States, E. F. SMITH (*Proc. Amer. Assoc. Adv. Sci.*, 48 (1889), p. 303).—The results of the author's studies on parasitic *Fusariums*, as shown by his completed experiments on soil infections with the watermelon fungus, are given. It is shown that related species of *Fusariums* prove equally destructive to other plants, such as cabbage, tomato, sweet potato, etc. It is also shown that these fungi live in the soil over winter and attack the plant from the earth. A soil once infected with any of these

resistant fungi becomes worthless for growing agricultural plants subject to it for a long series of years. On this account the greatest care should be taken to avoid the spread of these parasites to land which is now free from them.

The black rot of cabbage and similar plants in Europe, H. A. HARDING (*Centbl. Bakt. u. Par., 2. Abt., 6* (1900), No. 10, pp. 305-313, pls. 2, figs. 2).—An account is given of the author's investigations in Europe of the black rot of cabbage and similar plants, which has been attributed to a bacterial parasite, *Pseudomonas campestris*. He reports having observed the disease in the open field in about a dozen localities in northwestern Europe. The organism was isolated, cultivated, and comparisons made with the organism described by Smith and Russell in this country.

Infection experiments were conducted in pots in which the organisms isolated from diseased cabbages in New York and in Wisconsin were compared with the organism isolated from Swiss crucifers. At the termination of the experiments the organisms were compared, and no differences were noted between the bacteria derived from the different sources.

Observations on a disease of plum trees, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900*, pp. 218-227).—In a previous report (E. S. R., 9, p. 761) a description is given of a fungus disease which was proving fatal to standard plum trees at Harpenden. The disease at that time was attributed to *Nectria ditissima*, but subsequent investigations showed that this fungus was not the primary cause of the disease. In 1898 41 per cent of the whole plantation had been killed by the disease. The fungus seems to spread very rapidly. Trees which failed to show any signs of the disease when examined in the winter, were badly attacked before the following midsummer. From the tables given, it appears that old trees, 9 years or more old, were the greatest sufferers. Subsequent examinations in another locality of a disease which was believed to be the same showed the trouble was due to *Eutypella prunastri*. Successful inoculation experiments were conducted, which produced symptoms very similar to those exhibited by the trees at Woburn Farm. While not affirming that the diseases are identical, it is believed that the trees in each locality were suffering from the same cause. A curious feature in connection with this disease was the sudden disappearance of the disease in 1899. This sudden disappearance is explained by the possibility that the fungus fruits only under special climatic conditions, which were absent at this time.

Fungus diseases of citrus trees in Australia and their treatment, D. McALPINE (*Melbourne: Department of Agriculture, 1899*, pp. 132, pls. 31).—General descriptions and suggested methods of treatment are given of the principal diseases of citrus trees occurring

in Australia. In all, 82 species of fungi have been identified, 51 of which are new to science. Of these, 38 are said to be parasitic on different parts of citrus trees or fruits.

False melanose, anthracnose, sooty mold, black scurf, scabbing, wither tip, bark blotch, collar rot, and root rot of lemon are described at considerable length. The false melanose, which attacks not only the fruit but leaves and young shoots, is said to be due to *Cladosporium brunneo-atrum*, n. sp. The anthracnose, which is attributed to *Phoma citricarpa*, n. sp., is said to be quite common on fruits sold in the vicinity of Melbourne and Sydney. It causes considerable damage to the orange and lemon crops, spreading rapidly from fruit to fruit and from tree to tree. It is not to be confused with the leaf spot occurring in Florida on sweet and wild orange trees, which is caused by attacks of *Colletotrichum adustum*. The sooty mold of orange and lemon, caused by *Cynodidium citricolum*, is described at considerable length, and the relation between this disease and certain insects pointed out. The black scurf of citrus fruits is caused by *Coniothecium scabrum*, n. sp. The symptoms of this disease are said to be very characteristic. It first begins as small black depressions, causing the skin over a considerable area to become a yellowish green. It gradually spreads and forms large sooty, black patches, the epidermis cracking into minute irregular areas. In addition to making the fruit very unsightly, it renders it extremely liable to saprophytic fungi, causing decay. The scabbing of fruits and leaves is described, in which 11 different species of fungi are concerned, 6 of which are found upon the leaf. The wither tip of orange and lemon is attributed to *Phoma omnivora*, n. sp. It resembles to some extent the disease known in Florida as die-back, and the striking differences between the two are pointed out.

The lemon bark blotch, due to *Ascochyta corticola*, n. sp., is described. In this disease the trees from the collar upward for 6 or 8 in. become shriveled and studded with small brownish, thickly clustered bodies. The disease finally works all around the tree and the tree dies.

The collar rot, caused by *Fusarium limonis*, and the root rot of lemon, due to *Phoma omnivora*, are described. In part 2 technical descriptions of all the fungi found upon citrus trees are given.

The Graphiola disease of palm leaves, K. VON TUBELF (*Gartenflora*, 49 (1906), No. 6, pp. 148-150, fig. 1).—The author describes a disease of palm leaves which is characterized by the appearance of small black areas on both sides of the leaves. These occurring very abundantly give a blackened and unsightly appearance to the leaves and ultimately cause their destruction. The disease seems to be widely distributed and is caused by *Graphiola phenicis*, which occurs principally on the leaves of *Chamarops humilis*, but has not been previously

observed on the leaves of the date palm. Diseased leaves should be cut off and burned in order to prevent the spread of the disease. Sound plants may be sprayed with Bordeaux mixture, or the leaves may be washed with soapsuds or a weak solution of lysol to prevent the germination of spores.

A disease of conifers, G. MASSEE (*Gard. Chron.*, 3. ser., 27 (1900), No. 686, p. 101, fig. 1).—A report is given of attacks of *Sclerotinia fuckeliana* on Sequoias and other coniferous trees. When first observed, the portions attacked seemed to be covered with a dense outgrowth of gray mold. After the twigs were dead, numerous small black sclerotia, about the size of a pin's head, were found embedded in the bark and also in the tissues of the diseased and fallen leaves. Artificial infection of conidia have shown that Scotch fir and, perhaps, most conifers are susceptible to this disease. Other groups of plants, such as cherries, etc., have been artificially inoculated, but, on the whole, coniferous seedlings appear to suffer the most. When the disease appears, it spreads very rapidly, especially during damp, cloudy weather, and spraying with dilute Bordeaux mixture or what the author calls "violet mixture" should be resorted to as a check to prevent further spread. Experience has shown that plants once attacked invariably die; hence all diseased plants should be promptly removed and burned. The "violet mixture" recommended is said to adhere to the foliage better than the Bordeaux mixture and does not leave a white deposit on the plant sprayed. It is composed of copper sulphate 2 lbs., copper carbonate 3 lbs. permanganate of potash 3 oz., and water 18 gal.

New species of fungi, FLORA W. PATTERSON (*Bul. Torrey Bot. Club*, 27 (1900), No. 5, pp. 282-286).—Descriptions are given of 17 new species of fungi, many of which are parasitic. *Stemphylium butryi* is described as growing in butter, the surface of which gradually becomes a bluish black color.

New species of fungi, J. B. ELLIS and B. M. EVERHART (*Bul. Torrey Bot. Club*, 27 (1900), No. 11, pp. 571-578).—Descriptions are given of 27 new species of fungi, many of which are parasitic. The specimens are from various American localities.

The rusts of cereals, E. MARCHAL (*Jour. Soc. Agr. Brabant-Hainaut*, 1900, pp. 286-288).

The cereal rusts of Belgium, H. VANDERYST (*Rev. Gén. Agron.* [Louvain], 9 (1900), No. 8, pp. 359-368).—The author reports having observed 189 species, representing 17 genera, of Uredinæ in Belgium during the season of 1898. Brief notes are given on their distribution throughout the country.

Depreciation of the yields of cereals due to rusts, A. GRÉGOIRE (*Jour. Soc. Agr. Brabant-Hainaut*, 1900, p. 173).

The fungus diseases of the potato and their treatment, H. POTEL (*Bol. Inst. Agron. São Paulo*, 10 (1899), No. 11-12, pp. 795-799).

Fungus diseases of sweet potatoes, H. POTEL (*Bol. Agr. São Paulo*, 1. ser. 1900, No. 1, pp. 45-48).

The potato disease, its history and prevention, LAVERGNE (*Santiago*, 1900, pp. 10).

A disease of potatoes and melons in Santiago and Coquimbo, LAVERGNE (*Santiago*, 1900, pp. 12).

A sorghum disease in Usambara, STUHLMAN (Tropenpflanzer, 4 (1900), No. 11, pp. 561, 562).—A brief note is given on a disease of sorghum in Africa. The cause is not definitely known, and some varieties seem more subject to it than others.

Fungus diseases of the sugar beet (Beet Sugar Gaz., 2 (1900), No. 9, pp. 5-8, figs. 3).—Notes are given on root rot due to *Rhizoctonia* and on the leaf spot disease caused by *Cercospora beticola*.

The practical workings of seed treatment for prevention of diseases of sugar beets, B. FRANK (Bl. Zuckerrübenbau, 6 (1899), No. 5, pp. 65-68).

Notes on some fungus parasites of fruit trees, L. DE NOBELE (Bul. Arbor. et Flor., 1900, pp. 147-150).

Combating Fusicladium on fruit trees (Deut. Landw. Presse, 27 (1900), No. 91, pp. 1106, 1107, figs. 3).—The value of Bordeaux mixture as a means for the prevention of scab of apples and pears is shown. Three applications are recommended and the leaves in the autumn should be collected and burned.

Fungus pests of citrus trees (Agr. Jour. Cape Good Hope, 17 (1900), No. 7, pp. 421-424).—Brief popular descriptions are given of a number of principal fungus pests on citrus trees, which have been observed in Australia. The diseases described are false melanose, withered tip, anthracnose, sooty mold, black scurf, scab, bark blotch, collar rot, and root rot. Suggestions are given for the prevention of these different diseases, and among the fungicides recommended are Bordeaux mixture, a dilute solution of copper sulphate, ammoniacal copper carbonate, carbolic acid, sulphur, etc.

Some fungi of the cacao tree, J. H. HART (West Indian Bul., 1 (1900), No. 4, pp. 422-427, pl. 1).—Notes are given of attacks of *Phytophthora omnivora*, *Nectria bainii*, and an undescribed species of *Nectria*, all of which proved considerably injurious to the production of pods of cacao. The *Phytophthora* is said to diminish the weight of the pods fully 25 per cent. The beans are reduced at the same time and there is quite a depreciation in their quality.

Concerning the bacterial diseases of strawberries, P. VOGLINO (Ann. Accad. Agr. Torino, 42 (1899).

Fungus diseases of the grape (Oklahoma Sta. Rpt. 1900, pp. 104-107, figs. 3).—Brief descriptions are given of anthracnose, black rot, brown rot or downy mildew, and shelling or rattles of grapes, with suggestions for their prevention.

Rust, leaf spot, and anthracnose of grapes, L. BALDRATI (Italia Agr., 1900, No. 6, pp. 4).

Observations on grape anthracnose, J. CAPUS (Observations sur *Panthracnose maculée*. Bordeaux, 1900, pp. 15).

Variations in the maturing of *Plowrightia morbosa* spores, W. A. RILEY (Bul. Torrey Bot. Club, 27 (1900), No. 5, pp. 286, 287).—While studying the black knot fungus considerable variation was noticed in the time of maturing the ascospores. January has been given as the time for their maturation in Massachusetts, but in New York the first appearance was noted on March 7, and only by the middle of April were they fairly abundant. Examinations made as late as May 9 showed 75 per cent of the spores immature.

Practical directions for combating *Peronospora*, A. BIZZAZERO (Istruzioni pratiche per combattere la peronospora e la crittogama. Parma, 1900, pp. 29).

On the use of copper sulphate as a remedy for *Peronospora*, L. SOSTEGNI (Extr. Giorn. Viticol. e Enologia, 7 (1899), pp. 15).

The occurrence of the California vine disease in Avellino, C. CASALI and T. FERRARIS (Extr. Giorn. Viticol. e Enologia, 8 (1900), pp. 10, pls. 2).

Liver of sulphur for combating oidium, G. BATTANCHON (Vigne Amer. et Viticult. Europe, 24 (1900), No. 7, pp. 199-201).—A formula of potassium sulphid 500 gm., black soap 500 gm., and water 100 liters is given. The efficiency of the liver of sulphur is said to be increased by adding the soap.

A new disease of the leaves of *Aucuba japonica*, C. MASSALONGO (*Bul. Soc. Bot. Ital.*, 1900, pp. 166, 167).

Notes on outgrowths on the green parts of *Hibiscus vitifolius*, DALE (*Proc. Camb. Phil. Soc.*, 10 (1900), No. 4, pp. 192-209, pls. 3).

A disease of birch trees, R. PAULSON (*Nature*, 62 (1900), No. 1616, p. 599).—A brief note on the occurrence of a destructive disease of birch trees in parts of England. The cause of the disease is thought to be *Melanconis stilbostoma*, since that fungus is found abundant on both living and dead trees.

A contribution to the knowledge of an oak root parasite, R. HARTIG (*Centbl. Gesam. Forstw. Wien*, 26 (1900), No. 6, pp. 243-250, figs. 10).—Notes are given on the life history of *Rosellinia quercina*, a destructive parasite of oak roots. The most serious injury is to seedlings, although the author reports the perithecia of the fungus on old plants. The spores germinate readily in water after 24 hours, and retain their vitality for at least a year. The mycelium attacks the cellulose of the root, dissolving it and also uses up the starch in the roots.

Preliminary note on some witches' brooms, R. A. ROBERTSON (*Trans. and Proc. Bot. Soc. Edinburgh*, 21 (1900), pt. 4, pp. 313-318, figs. 2).—Notes are given of witches' brooms observed on the larch and *Picea nobilis*. These formations are well known on some coniferous trees, but on the species mentioned they are comparatively rare. Other witches' brooms are reported as occurring on ash (*Fraxinus excelsior*), and upon *Crataegus oxyacantha*. The author states he has been unable to find any record of such outgrowths occurring on either of these species.

The adhesiveness of potassium permanganate as a fungicide, G. CHAPPAZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 47, p. 625).—As a result of a single application in June, traces of the permanganate were found upon the grape leaves in autumn.

A disinfecting machine for cereals, F. FALKE (*Landw. Wchenschr. Sachsen*, 2 (1900), Nos. 41, pp. 365-367; 42, pp. 374, 375).—A description is given of a machine designed for the rapid treatment of cereals with formalin or formalin and ammonia for smut prevention. Comparative figures are also given in which the efficiency of the treatment is shown as well as the effect upon the germination of the seed.

A review of the literature relating to plant protection during 1899, M. HOLLRUNG (*Jahresbericht über die Neuerungen und Leistungen auf dem Gebiete des Pflanzenschutzes*, Berlin, 1900, pp. 303).—Brief reviews are given of the general literature relating to fungus diseases and insect enemies of plants and the means taken for combating them. In the second part the literature pertaining to these injurious agents is grouped according to the host plants, the principal groups being: Injuries to plants without reference to the hosts; injuries to cereals, to fodder grasses, root crops, garden crops, forage crops other than grasses, large and small fruits, grapes, tropical plants, forest trees, and ornamentals. The means for combating these diseases are divided into natural and artificial methods, the latter referring to chemical and mechanical agencies, while the former refers to parasites, etc. An annotated list of nearly a hundred pages of titles of publications in addition to those abstracted at greater length completes the volume and serves to give some idea of the extent of the literature upon the subject.

ENTOMOLOGY.

Apiary experiments, C. P. GILLETTE (*Colorado Sta. Bul.* 54, pp. 28, pls. 6).—The general problem with which this bulletin is concerned is the question to what extent and in what form wax can be best furnished to bees for their use in building comb. As is well known, it is generally believed that bees use wax from artificial foun-

dations to extend the cell walls and the comb midrib. This belief was shown to be well founded by a simple experiment, during which sheets of thin foundation rendered black by the addition of lampblack were employed. It was found that the wax used both for the extension of the midrib and the formation of cell walls contained lampblack.

The author measured a number of artificial foundations of comb midrib built upon such foundations and a natural midrib of comb. The evidence confirms that obtained by weighing the same structures, that heavy foundations are somewhat thinned by the bees in constructing comb upon them, but that these foundations are not thinned in any case to the lightness of natural comb.

To determine whether the use of artificial foundations results in thicker cell walls in the comb, experiments were made with several kinds of foundation, measurements being made with the camera lucida and a compound microscope. The cell wall in natural worker comb varied from 0.045 to 0.07 mm., with an average of 0.06 mm. None of the artificial foundations gave as thin cell walls except, perhaps, the thin and extra thin super foundations. The author concludes from this experiment that it is a mistake to make deep cells in artificial foundation unless their walls can be rendered as thin as those of the natural cell walls. The only cell walls which were brought to the thinness of the natural comb were those which were built on foundations with a light base and with little wax in the cell walls. To study the effect of foundations upon the resulting comb, pieces of natural comb and comb on different kinds of foundation were cut into blocks of known area and weight, the cell walls were then removed from the midribs, and the two portions weighed separately. The weights of the midribs and cell walls of natural comb were compared with corresponding parts of comb from artificial foundations. The evidence leads to the conclusion that heavy foundations result in combs which are heavier than the natural combs, and that the increased weight is due both to thicker midribs and thicker cell walls, but more especially to the latter. The evidence shows also that if the cell walls are high they are not often thinned by the bees in constructing the comb.

Studies of the extent to which the use of foundation lessens the secretion of wax by bees were made by a similar series of weight determinations. The evidence furnished by the weights of 49 samples of comb indicates that the wax secretion by bees is not any more influenced by furnishing them with a heavy foundation than by the use of a light foundation.

With regard to the methods of using foundation in sections, the author found that by using a long piece of foundation gradually tapering to a point, with a broad base attached to the upper edge of the section, the bees showed a tendency to form worker comb throughout.

The best results, however, were obtained by using a long narrow piece placed across the top of the section, or a rectangular starter extending about halfway down the section.

The use of wooden or tin separators between the rows of sections is strongly advocated by the author, since by their use the sections are rendered much more regular.

By determinations of the weight of different samples of comb honey it was found that the weight of the wax in thick combs is proportionately less than in thin combs, the proportion varying from 1:19 to 1:28.

The author tried a number of substitutes for pollen, the substances being laid upon flat boards in the vicinity of the apiary. A small pile of each kind of meal was put upon the different boards, and notes were taken upon the apparent frequency with which the different kinds were visited. The order of preference appeared to be as follows: Ground whole kernels of oats, corn, wheat, fine wheat bran, cleaner dust, cotton-seed meal, wheat bran, pea meal, wheat flour, rye flour, bean meal, and barley meal.

Bee poison and bee stings, J. LANGER (*Sitzber. Deut. Naturw. Med. Ver. Böhmen, n. ser.*, 19 (1899), pp. 291-310). Bee poison has an acid reaction, but its toxic action is not due to formic acid. It is free from bacteria and has the effect of slightly checking the growth of micro-organisms. The author made observations on the sensitiveness of different persons to bee poison. Of the individuals upon whom observations were made, 11 were not sensitive to the poison, and 153 were sensitive when they first began the business of bee culture. Brief notes are given on the various remedies which are popularly employed for the treatment of bee stings. The author recommends that in the case of persons who are oversensitive to the action of this substance, chemical antidotes should be applied at the point of the sting by means of a hypodermic syringe.

On the metamorphosis of the young form of *Filaria bancrofti* in the body of *Culex ciliaris*, the house mosquito of Australia, T. L. BANCROFT (*Jour. and Proc. Roy. Soc. New South Wales*, 33 (1899), pp. 48-62, figs. 8).—The author gives a brief critical account of the literature relating to this subject. It was found by experiments that the *Filariae* do not develop so rapidly in the body of mosquitoes as had hitherto been suspected. According to the author's experiments, the time required for this development is 17 or 18 days. The *Filaria* is first taken into the alimentary tract along with the blood sucked from the host of the mosquito and later penetrates into the thorax. All *Filariae* which are for any reason unable to make their way to the thorax of the mosquito ultimately die or, at least, fail to produce young *Filariae*. The juices of the alimentary tract seem to have an injurious effect upon them and they are in some cases killed outright and digested by these fluids. In dissecting mosquitoes infested with

Filariæ in water, it was found that the Filariæ died after remaining 3 or 4 hours in water. It is therefore believed by the author that infection of man by Filariæ can not take place from drinking water. An account is given of various details in the life history of the *F. bancrofti*.

Natural enemies and insecticide treatments for the larvæ of *Pieris brassicæ*, G. DEL GUERCIO (*Atti. R. Accad. Econ. Agr. Georg. Firenze*, 4. ser., 23 (1900), No. 2, pp. 242-254, figs. 3).—Hand picking of the larvæ and eggs of this species is more practicable than in the case of *P. rapæ* and *P. napi* for the reason that in the latter 2 species the larvæ are found on the under side of the leaves and the eggs are laid in small clusters or isolated.

The insecticides used against *P. brassicæ* included superphosphate of lime, emulsions of potash and soda soaps, emulsions of petroleum, benzine, and bisulphid of carbon, emulsions of heavy oil of tar and of creolin, carbolized extract of tobacco, and a solution of alkaline tar. Applications of superphosphate of lime at the rate of 500 kg. per hectare had no noticeable effect upon caterpillars. Emulsions of potash soap, in which the soap constituted from $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent of the emulsion, were quite effective remedies. Soda soaps in from $2\frac{1}{2}$ to $3\frac{1}{2}$ per cent solution of water gave good results. Emulsions of oil of tar, creolin, and similar substances when used as insecticides against the larvæ of the cabbage butterfly left a disagreeable odor upon the cabbage plants and are therefore not recommended.

The author describes and gives brief notes upon a considerable number of insect parasites and enemies of the cabbage butterfly. The percentage of caterpillars parasitized by the more important species are tabulated and the importance of insect parasitism of the cabbage butterfly is discussed in connection with this table.

Moth borer in sugar cane (*Diatræa saccharalis*), H. MAXWELL-LEFROY (*West Indian Bul.*, 1 (1900), No. 4, pp. 327-353, figs. 10).—The author reviews the literature relating to this subject. Detailed descriptions are given of the insect in all its stages. The eggs are laid on the surface of the leaf in clusters numbering about 19. The author gives notes on 2 insect parasites, *Trichogramma pretiosa* and *Cordyceps barberi*. As soon as the young leaves of the sugar cane are up, the moth borer begins its attack which results in producing "dead hearts" early in the year. The attacks of the moth borer render subsequent infestation by the rind fungus (*Trichosphaeria sacchari*) more easy. All varieties of cane are attacked by the moth borer, which has been found also upon a considerable number of other plants. A detailed discussion is given of the remedies which have been recommended by various committees of planters and by agricultural societies. The more important remedies may be briefly stated as follows: Careful selection of canes for planting, pruning of dried and decayed canes, destruction of diseased canes and the stumps of canes, and the use of

lantern traps for catching the moths. The author recommends also the collection of eggs which may be recognized on leaves. Care should be exercised, however, to leave all parasitized eggs so that the parasites may hatch and assist in reducing the numbers of the moth borer. An extensive bibliography of the subject is added to the article.

A report on methods of combating the grape *Cochylis* by winter treatment, J. LABORDE (*Bul. Min. Agr. [France]*, 19 (1900), No. 3, pp. 373-392).—The author states that the name *Cochylis* has been applied to two insects, *Tinea ambiguaella* and *Eudemis botrana*. The insects were studied in the laboratory in all of their stages. Several parasites were reared from each of these insects. Chrysalids maintained for 24 hours at a temperature of -10 to 12° C. were unharmed by the exposure. Chrysalids of *Eudemis* plunged for one minute in water at a temperature of 40° died to the extent of 20 per cent. A similar exposure in water at 50° C. killed all the chrysalids.

Among the chief remedies applied by the author mention should be made of scraping the bark, plunging the grape stocks in hot water, and painting with various mixtures. It is stated that painting with a mixture composed of lime, heavy oil, and bisulphid of carbon is very effective in destroying the insects and may be used without causing injury to the grape vines.

The grape-cane gall maker and its enemies, F. M. WEBSTER (*Ohio Sta. Bul.* 116, pp. 195-198, pl. 1).—The author's observations on this insect are confined to vineyards near Gypsum, Ohio. The galls produced by the beetle are always provided with an opening which does not heal until after the escape of the adult insects. The author believes that the complete life cycle is passed inside the galls. Fallen leaves collected near a vineyard on May 6, 1898, were placed in the insectary and adult beetles began to emerge from the mass of leaves on May 23. In the vineyard, near where the leaves were collected, numerous galls containing larvæ were found on June 24. All stages of the insect were found in these galls on August 11, and at this time some of the adults were already emerging. The life history of the insect may therefore be described as follows: The eggs, deposited in May or June, hatch into larvæ which live in the galls formed on the canes and finally transform into adults which leave the vines and pass the winter under fallen leaves or matted grass.

Catolaccus tylosdermæ is mentioned as an important parasite of this insect. The beetle seems to prefer the Concord variety, and it is recommended that this variety be planted in the central portion of the vineyard. The author suggests as a preventive measure the collection and destruction of fallen leaves and other rubbish in the vicinity of vineyards.

Fumigation with hydrocyanic-acid gas, A. D. HALL (*Bd. Agr. [London]*, *Rpt. Agr. Education and Research*, 1899-1900, pp. 71-73).—Experiments were conducted for the purpose of determining the

value of hydrocyanic-acid gas as a remedy for the black currant bud mite. Two thousand infested currant bushes were tied in bundles, placed in a heap on the ground, and the whole covered with water-proof cloth. In a small vessel in the center of the heap of bushes the author placed 100 cc. of water, an equal quantity of strong sulphuric acid and 36 gm. of 98 per cent cyanid of potash. After 1 hour the cloth was removed and a microscopical examination failed to show any living mites or eggs. The bushes were subsequently planted out and kept under observation. At present indications point to a complete destruction of the mite. Successful results with the same treatment were also obtained with large bushes planted in the field. The author believes the results of his experiments should encourage fruit growers to make a thorough trial of fumigation with hydrocyanic-acid gas for such insect pests as do not yield to ordinary treatment. Brief suggestions are given concerning the application of this method to green-houses and against the mealy bug and other insect pests.

An historical account of apiculture in connection with its fate in Siberia and Transbaikal, A. KUZNETZOV (*Istoricheskii ocherk pchelovodstva v soyazi s sudboyu ego v Sibiri i Zabaikalye*. Chita: 1899, pp. 13; rev. in *Selsk. Khoz. i Lysov*, 196 (1900), Jan., pp. 191, 192).—In Siberia apiculture has undergone its greatest development in Altai. Detailed accounts are given by the author of the conditions which are favorable to the rearing of bees and upon the connection of this industry with fruit raising.

The migration of insects, K. SAJO (*Prometheus*, 10 (1900), Nos. 515, pp. 737-741; 516, pp. 758-761, figs. 9; 517, pp. 770-772, fig. 1; 518, pp. 785-789; 519, pp. 802-806; 520, pp. 817-821).—The author presents a general discussion of the means of distribution of insects with special reference to their larger migratory movements. The climatic and other conditions which may in any way influence such movements of insects are also considered. Among the species to which special attention is given mention may be made of *Blissus leucopterus*, *B. doriae*, *Baris scolopacea*, *Phylloxera vastatrix*, *Otiorrhynchus ligustici*, *Porthetria dispar*, *Cheimatobia brumata*, *Vanessa cardui*, species of *Pieris*, and *Pachytylus migratorius*.

Experimental proof of the mosquito malaria theory, P. MANSON (*British Med. Jour.*, 1900, No. 2074, pp. 949-951, figs. 2).—An experiment was tried in importing mosquitoes from Italy which had sucked the blood of malarial patients. These mosquitoes were allowed to puncture the skin of the hand with the result that a typical case of malarial fever developed. A wooden hut, constructed in England, was shipped to Italy and placed in a locality which was ascertained to be intensely malarial. Five persons entered on a residence in this hut early in July. On September 21, when the last report was made, no case of malaria had developed among the experimenters, although the neighbors were all suffering from malaria or had had attacks. For the control of malaria the author recommends the drainage of the breeding pools of *Anopheles* and protection from mosquito bites.

The relationship of drinking water, water logging, and the distribution of *Anopheles* mosquitoes, respectively, to the prevalence of malaria north of Calcutta, L. ROGERS (*Proc. Asiatic Soc. Bengal*, 7 (1900), July, pp. 90-98).—The author, while admitting the agency of mosquitoes in transmitting malaria, believes that a total destruction of mosquitoes, even in a small area, is practically impossible.

The kissing bug, P. J. PARROTT (*Industrialist*, 27 (1900), No. 1, pp. 1-4, figs. 3).—Notes on the more common species of bugs in Kansas which have received this pop-

ular name, among which the following may be mentioned: *Melanolestes picipes*, *Conorhinus sanguisuga*, and *Opsicetus personatus*.

Observations on itch mites, J. BRANDL and F. GMEINER (*Wchnschr. Tierheilk. u. Viehzucht*, 44 (1900), No. 15, pp. 137-143).—An account of the literature which deals with the effects of various insecticide substances upon species of mites affecting domestic animals.

The Hottentot bug (*Eurygaster maurus*), T. ZOLOTILOV (*Selsk Khoz. i Lyesov*, 196 (1900), Feb., pp. 441-450).—This insect is reported as injurious to grain, both when young and when filling. Rye, wheat, corn, and sunflowers are attacked; also oats to a slight extent. Barley and millet are not injured by this species. As remedial measures the author recommends burning the stubble and planting barley and millet around the fields of wheat and rye.—P. FIREMAN.

Men and horses partially incapacitated by the bites of *Simulium* in a Hampshire wood, J. CANTLIE (*British Med. Jour.*, 1900, No. 2052, p. 1053).—Brief notes are given of an attack of a species of *Simulium* upon men and horses. Considerable local pain and œdema were produced by the bite.

Miscellaneous insects, H. E. SUMMERS (*Iowa Sta. Bul.* 49, pp. 9, figs. 7).—The Buffalo tree hopper (*Cercsa bubalus*) is believed to have been the most important apple insect in Iowa for the past two years. It attacks also the cherry, and has been occasionally observed laying its eggs in the pear, plum, peach, cottonwood, maple, willow, and elm.

The snowy tree cricket (*Oceanthus niveus*) is considered the most serious insect enemy of the raspberry in the State. The box-elder plant bug (*Leptocoris trivittatus*) sometimes causes injury to the fruit of the peach, plum, and apple. The approved remedies are recommended for the destruction of each of these insects.

Some insects injurious to fruit, B. F. MACCARTNEY (*Pennsylvania Dept. Agr. Rpt.* 1899, pl. 1, pp. 88-122, figs. 44).—This report contains popular notes on a large number of insects affecting apple, pear, plum, peach, cherry, grape, raspberry, blackberry, currants, gooseberries, strawberries, shade trees, and clover.

Report on a disease of plum trees in the neighborhood of Villeneuve-sur-Lot, PRILLIEUX and DELACROIX (*Bul. Min. Agr. [France]*, 19 (1900), No 1, pp. 67-75).—The authors report serious depredations by *Scolytus rugulosus* upon plum trees. Brief notes are given upon the life history and habits of this beetle. It is believed that the beetles may be instrumental in carrying the spores of certain fungi which assist in the weakening or destruction of the trees. It is recommended that very badly infested trees should be destroyed with the insects and that plum orchards should be well cared for in order to keep the trees in vigorous condition and thus render them more resistant to the attacks of the bark beetle.

The San José scale, J. M. SOUTHWICK (*Rhode Island State Bd. Agr. Bul.* 7, pp. 6).—Brief biological and economic notes on this insect.

Treatment of the woolly aphis, H. DAUTHENAY (*Rev. Hort.*, 72 (1900), No 19, pp. 557, 558).—Brief notes on the results of experiments with two insecticides made as follows: (1) Water, 10 liters; acetic acid, 1,000 gm.; salicylic acid, 2 gm.; red oxid of mercury, 1 gm.; and fuchsine, 25 gm.; (2) creolin, 35 gm.; black soap, 35 gm.; and water, 1 liter.

Plant lice, E. HENNING (*Landtmannen*, 11 (1900), No. 31, pp. 490-492, fig 1).—Biological and economic notes on phylloxera, woolly aphis, *Tetraneura ulmi*, and *Aphis persicae niger*.

Kerosene emulsion and lysol as remedies for plant lice on fruit trees (*Landtmannen*, 11 (1900), No. 26, pp. 420-422, figs. 2).—Kerosene emulsion proved to be especially effective as an insecticide against these insects.

Insects affecting the grape, E. E. BOGUE (*Oklahoma Sta. Rpt.* 1900, pp. 108-115, figs. 4).—Notes on the habits, life history, and remedies for the stem borer, gray

skeletonizer, spotted vine chafer, brown-backed skeletonizer, grapevine leaf folder, rose chafer, and grape-berry moth. Formulas are given for preparing Bordeaux mixture, ammoniacal solution of copper carbonate, potassium sulphid, Paris green, kerosene emulsion, hellebore, and pyrethrum.

Some results of experiments in spraying at the Central Experiment Farm in 1899, W. T. MACOUN (*Ontario Fruit Growers' Assoc. Rpt. 1899*, pp. 100-109).—During experiments in spraying trees with whitewash to determine the effect of this substance in retarding bug development in early spring, it was noticed that the oyster-shell bark louse, which had resisted all other insecticide applications, was entirely destroyed. The whitewash was made of 6 gal. of skim milk, 24 gal. of water, and 60 lbs. of lime. The author believes that this remedy may prove effective in combating the San Jose scale. Brief notes are given on the means of distribution of the codling moth.

The advantages of fumigation, J. W. JEFFREY (*California Cultivator*, 15 (1900), No. 7, pp. 97, 103).—A popular discussion of the method of fumigation and of practical advantages derived from its application.

A note on the use of bisulphid of carbon on a large scale, V. VERMOREL (*Note sur l'emploi du sulfure de carbone en grande culture. Villefranche (Rhône) and Montpellier: Progres Agricole et Viticole* [1900], pp. 12).—This pamphlet contains a brief account of the value of bisulphid of carbon in treating grapevines for phylloxera and in similar applications of this substance. The influence of bisulphid of carbon upon the soil is also discussed.

Insecticide methods, H. E. SUMMERS (*Iowa Sta. Bul. 50*, pp. 13-23).—The author presents a general account of mechanical and chemical methods for combating injurious insects. Among the former are included barriers, trunk washes, worming, hopperdozers, burning, and hand picking. Among the chemical methods reference is made to Paris green, London purple, arsenite of lime, arsenate of lead, resin lime mixture, kerosene, kerosene emulsion, tobacco infusion, whale-oil soap, pyrethrum, hydrocyanic-acid gas, carbon bisulphid, and Bordeaux mixture.

Russian literature in entomology since 1896, N. KULAGIN (*Opuit o literaturje po nasyekomuim za 1896. Moscow: Ministry of Agriculture and Imperial Domains, 1900*, pp. 61; *abs. in Selsk. Khoz. i Lyesov*, 196 (1900), March, pp. 719, 720).

FOODS—ANIMAL PRODUCTION.

Cellulose and pentosans in feeding stuffs, I. SHIROKIKH (*Selsk. Khoz. i Lyesov.*, 195 (1899), Oct., pp. 121-144).—The great diversity of views regarding the nutritive value of cellulose is, in the opinion of the author, largely due to the fact that the crude fiber has been considered, rather than the cellulose and the pentosans separately. He reports an investigation in which these were considered separately.

To study the digestion of cellulose, experiments were made with sheep and rabbits. The sheep were fed from 4 to 7 days and then killed 6 to 12 hours after the last meal. The digestive organs, with their contents, were then detached and cut into 13 parts. The contents of each part were weighed separately, then dried and analyzed. When hay and coarse fodders were fed, it was found that while the food is in the paunch a larger or smaller part of the cellulose (up to one-third of the total quantity) dissolves, and in the third stomach a smaller percentage of it is found than in the food as eaten. As the

food passes from the third to the fourth stomach (abomasum), and especially from the latter into the small intestines, the percentage of cellulose falls very low, which is connected chiefly with the admixture of the intestinal juice but also probably with the solution of cellulose. From the middle of the small intestines the percentage of cellulose again increases, this increase continuing to the excretion of the feces, except in the blind intestine, where the increase is prevented by the more energetic decomposition of the cellulose, which exceeds the absorption of all the dissolved parts of the food.

With tender or green food the results were somewhat different. Thus, in the case of one sheep fed green oats the percentage of cellulose in the paunch remained unchanged, and, what is especially important, even on passing into the third stomach the percentage of cellulose was not lowered but increased slightly. The amount of the other components of the fodder, except the starch, also remained practically unchanged. In connection with this circumstance the following is noted: When hay (clover and timothy) was fed, judging from the feces 72 hours were required for the passage of the fodder through the alimentary canal, and it is assumed that the fodder remained in the paunch for 48 to 54 hours, while the remaining 24 hours, or possibly only 18 hours, were required for the passage of the small intestines and the blind intestine. On the other hand, when grass was fed, the fodder remained in the alimentary canal not longer than 36 hours, of which only 12 to 18 hours were required in the paunch. As to the changes of the cellulose content in the parts of the alimentary canal beyond the third stomach, no difference is observed when feeding with hay and with grass.

In herbivora, other than ruminants, the changes of the cellulose content are different. Experiments were made with rabbits, of which 3 were fed with hay, 1 with green grass, 2 with peas, and 3 with hay. The latter were young rabbits. The experiments showed concordantly that here the main part of the cellulose is decomposed in the blind intestine.

In the foregoing experiments only the comparative amounts of cellulose in the various parts of the alimentary canal were considered. The absolute amounts of cellulose digested were studied in an experiment with a horse and a sheep. The experiment with the sheep lasted 6 days, 965 gm. of meadow hay per day being consumed. The horse received an average of 18 lbs. of hay per day. The digestibility was as follows:

Fiber, cellulose, and pentosans digested by a horse and sheep.

	Experiment with a sheep.			Experiment with a horse.		
	In the hay consumed.	In the feces excreted.	Coefficient of digestibility.	In the hay consumed.	In the feces excreted.	Coefficient of digestibility.
	<i>Gm.</i>	<i>Gm.</i>	<i>Per ct.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Per ct.</i>
Organic matter	795	281	64	6,263	3,042	51
Pentosans	171	65	62.6	1,005	670	33
Crude fiber	288	105	65	1,938.2	1,306.5	33
Cellulose	260	74	71.5	1,760	862	51

In the case of the sheep the digestibility of the fiber corresponds to the mean value given by Wolff for sheep. The digestibility of the pure cellulose is greater than that of the fiber. The digestibility of the pentosans, on the contrary, is not only lower than that of cellulose and fiber, but is somewhat lower than that of the total organic matter. This is still more marked with the horse.

Considering the ratio between the cellulose and the pentosans as found in the experiment with sheep, it is shown that the ratio in the hay is first altered in the third stomach. This may be due to the fact that cellulose is more easily decomposed by micro-organisms than pentosans, and hence is destroyed in the paunch to a greater extent. In the small intestines, where the intestinal juice is supposed to take part in dissolving the cellulose and the pentosans, the ratio remains unchanged; but in the blind intestine, where the cellulose is again subjected to strong decomposition by bacteria, the ratio of pentosans increases. In the case of the rabbit, the difference in the digestibility of the cellulose and the pentosans is also more marked in the blind intestine.

On the basis of these experiments it is stated that the digestion of starch differs essentially from the decomposition of cellulose in the alimentary canal. The products of the digestion of starch and cellulose must, therefore, be very different. Hence the nutritive value of the substances in question must be quite different, not to mention the difference in loss of energy due to digestion.

As to the nature of the digestion of pentosans, the similarity of the changes in the different parts of the alimentary canal indicates that the nature and the products of their digestion resemble those of cellulose rather than those of starch.—P. FIREMAN.

The digestibility of some nonnitrogenous constituents of certain feeding stuffs, G. S. FRAPS (*North Carolina Sta. Bul. 172, pp. 49-68, 70-80*).—Using the data obtained in digestion experiments made with sheep on several feeding stuffs, reported in earlier bulletins of the station (E. S. R., 10, p. 667; 11, p. 276), and one on timothy hay not yet reported, the author estimated the digestibility of several constituents

of the carbohydrate group. The methods followed are described. The following table summarizes the results obtained:

Coefficients of digestibility of different constituents of the carbohydrate group—Experiments with sheep.

	Total dry matter.	Total sugars.	Nitrogen-free extract.	Nitrogen-free extract less sugars.	Total pentosans.	Pentosans in nitrogen-free extract.	Nitrogen-free extract less pentosans and sugars.	Crude fiber.	Pentosans in crude fiber.	Crude fiber less pentosans.	Pentosans left by 2.22 per cent acid.

The experiments are discussed in relation to similar work at other stations. The author's principal deductions follow:

"Sugars are found in all feeding stuffs, sometimes in large percentages are completely digested, and their determination is of importance in the case of hays and cotton-seed meal. Subtraction of sugars from the nitrogen-free extract of hays reduces its digestibility appreciably. With concentrated feeding stuffs the reduction is slight.

"The total pentosans are distributed between the nitrogen-free extract and the crude fiber. The former are here called true pentosans, the latter pseudo-pentosans. The true pentosans have a higher coefficient of digestibility than the pseudo-pentosans. They form from 79.3 to 100 per cent of the total pentosans. True pentosans and sugars make up from 22 to 52.6 per cent of the nitrogen-free extract.

"The constituents of the nitrogen-free extract can be arranged in the following order, according to their digestibility: (1) sugar, (2) starch, (3) pentosans, (4) remainder. Crude fiber may be divided into pseudo-pentosans and residue. The pseudo-pentosans make up from 0 to 14.4 per cent of the crude fiber, and are less digestible, as a rule."

Cod-liver oil for calves (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1899-1900, pp. 107-109*).—The Yorkshire College reports tests of the value of cod-liver oil as a substitute for milk fat and for meal in feeding calves. Calves fed on whole milk for 12

weeks gained 1.8 lbs. per day. Those fed about a half ounce of cod-liver oil in addition to separator skim milk gained 1.6 lbs. per day; while those fed separator skim milk and a mixture of linseed meal, oat meal, rice meal and locust-bean meal, 2:1:1:1 (so-called calf meal), gained 1.3 lbs. per head daily.

"The result of the experiment indicates that cod-liver oil can be recommended with some confidence as a substitute for cream and also for meal in rearing calves, but caution should be exercised in the use of cheap brands of cod-liver oil; in the above experiments the oil used was of the very best quality. No experiments were made to demonstrate whether more than 2 oz. of oil per day would be beneficial. A larger quantity appeared to keep the bowels too open, but this looseness of the bowels seemed to be quite distinct from ordinary scour, inasmuch as the calves were not unthrifty."

The value of whole milk for the production of veal, H. HAYWARD (*Pennsylvania Sta. Rpt. 1899, pp. 142-159*).—Details are given of 2 tests of the value of whole milk for calves. In the first test 6 calves from 3 to 14 days old, ranging in weight from 59 to 85 lbs. at the beginning of the trial, were fed. The average weekly gain ranged from 9.1 to 16 lbs. in the first 4 weeks. Up to this time the calves had consumed on an average 393.2 lbs. of milk containing 17.5 lbs. of fat. If they had been sold at this time at $4\frac{1}{2}$ cts. a pound, the author calculates that they would have brought \$4.73 per calf, an equivalent of \$1.20 per hundred for the milk consumed. "If the amount of butter fed the calves during this period is estimated in the usual way by adding $12\frac{1}{2}$ per cent to the butter fat, the equivalent price of butter would have been 24 cts. per pound." The feeding was continued for 4 weeks longer, the average weekly gain being $12\frac{1}{2}$, 13.8, 6.75 and 13.2 lbs., respectively. The amount of milk required per pound ranged from 7.4 to 18.1 lbs., and the amount of fat from 0.38 to 0.77 lb. Two of the calves were sold at the end of the sixth week of the test, 2 at the end of the seventh, and the remaining 2 at the close of the trial.

On the basis of the data obtained in this and the following tests the author calculates the relative value of butter fat when made into butter or when used for the production of veal, when this ranges from 4 to $6\frac{1}{2}$ cts. per pound.

A second test was made with 8 calves weighing from 58 to 80 lbs. at the beginning of the trial, the calves being fed whole milk from about 5 to 7 weeks. According to the author, "with a feeding period a little over 6 weeks in length, the average veal calves paid 95.7 cts. per hundred for milk testing approximately 4.05 per cent, or 20.9 cts. for butter thus consumed. The average yearly price paid for butter on the Elgin Board of Trade in 1898 was 18.8 cts. If from this is deducted the cost of making, the net price will be a little more than 15 cts., or about 6 cts. less per pound than could be obtained for it if fed to veals and sold at $4\frac{1}{2}$ cts. per pound at 6 weeks of age."

From the 2 tests the following conclusions are drawn: "New whole

milk fed to average calves until they were 7 weeks old yielded more satisfactory returns than if it had been manufactured into butter and sold at the average market price for creamery butter. There was little difference in the amount of milk required to produce a pound of gain from the first to the seventh week of feeding, the average being 9.8 lbs. of milk testing 4.2 per cent fat."

Corn, Kafir corn, and alfalfa as beef producers, F. C. BURTIS (*Oklahoma Sta. Rpt. 1900, pp. 84-89*).—Using 4 lots of 5 steers each, averaging about 976 lbs. in weight the feeding value of Kafir corn meal and corn-meal feed with alfalfa hay and with corn stover was tested. In 112 days the average daily gains of the steers on the different rations were as follows: Kafir corn meal and alfalfa, 2.34 lbs.; corn meal and alfalfa, 2.54 lbs.; Kafir corn meal and Kafir corn stover, 2.33 lbs.; and corn meal and Kafir corn stover, 2.01 lbs. The grain eaten per pound of gain by the 4 lots was 7.35, 7, 10.58, and 9.3 lbs., respectively. The corresponding cost per pound of gain was 5.24, 4.92, 5.56, and 5.18 cts. The coarse fodder eaten with a bushel of grain varied from 0.43 lb. in the case of Kafir corn meal and corn stover to 0.56 lb. in case of Kafir corn meal and alfalfa.

Cotton seed and cotton-seed meal were substituted for the coarse fodder and the feeding continued for 35 days, the average daily gains of the 4 lots being 2.6, 3.2, 2.45, and 2.99 lbs., respectively. The grain eaten per pound of gain was 8.02, 6.54, 8.73, and 7.01 lbs., respectively, while the corresponding cost per pound of gain was 5.9, 4.8, 6.34, and 5.08 cts.

The steers were shipped and slaughtered. When dressed, the carcasses weighed from 59.21 to 61.71 per cent of the weight before slaughtering. The total profit on the steers was \$152.48. Four pigs ran after each lot of steers, but the results obtained are not reported.

In the author's opinion the test emphasizes the value of alfalfa hay, and should encourage Oklahoma farmers to raise more of this crop.

Cattle feeding, H. T. FRENCH (*Idaho Sta. Bul. 24, pp. 12*).—The possibility of profitably fattening steers under local conditions was tested with 3 lots of 4 animals each. The steers were kept in stalls and spent a portion of each day in small yards. The test began January 1 and covered 3 months. The first month the average daily ration fed all the steers consisted of 30 lbs. of silage, 10 lbs. of grain (chopped wheat and bran, 4.6), and 5 lbs. chopped oat hay. During the second month, 20 lbs. of mangel-wurzels were substituted for the silage fed lot 1, the grain and oat hay being also somewhat modified. Lots 2 and 3 were fed much the same ration as during the first month. During the third month of the trial the rations fed all the lots were much the same as during the second, except that 10 lbs. of roots per steer was added to the rations of lots 2 and 3, the silage being decreased an equal amount. Each lot weighed somewhat over 3,400 lbs. at the beginning of the trial.

The average daily gain of the steers of the 3 lots was 1.20, 1.72, and 1.37 lbs. The steers were slaughtered, the average dressed weight being a little over 60 per cent of the live weight. According to the author, the quality of the meat was all that could be desired. The fat and lean were well distributed, and the fat was light in color. The financial aspect of the test is discussed, the average profit per steer being estimated at \$12.52.

"While the average daily gain was not wholly satisfactory, it will compare favorably with that made by cattle fed in the corn States. The results are sufficiently encouraging to warrant more stock feeding in this section. Two-year-old steers can be matured on the grains and fodders produced in this section. There is a profit in keeping steers for winter feeding instead of selling an inferior and cheaper product in the fall. Corn silage can be successfully used in feeding steers in this locality."

Economical production of beef, C. F. CURTISS and J. A. CRAIG (*Iowa Sta. Bul.* 48, pp. 340-372, figs. 9).—Feeding tests extending over a number of years are reported. Regarding the possibilities of combined dairying and feeding for beef production, a feeding experiment with 14 steers, begun in December, 1896, and covering 2 years, is reported. The feeding of these animals as calves has been previously noted (*E. S. R.*, 9, p. 973). During the test considered as a whole, the steers were fed skim milk, different grains, and coarse fodders, etc. The average daily gain in the whole period was 1.72 lbs. per head; the cost of a pound of gain, 4.09 cts. The steers were sold in Chicago, the dressed weight being 64.4 per cent of the live weight. The total profit per head was \$12.22.

"From the results so far obtained through these trials it is evident that a system whereby dairying and meat making may be combined is the most promising in profits. Not only do the steers from cows bred with this combination in view yield as much profit as those from the range, but the returns from the cows when used for dairy purposes makes the combination much more remunerative. The data secured through the actual work of establishing a herd of this kind and the actual test of the cows in the dairy and steers in the feed lot show that it is not only possible to combine these qualities to a profitable degree, but also to perpetuate them if the herd is bred especially for them.

"In the economical production of beef through a combination of dairying and beef making it is very necessary that the calves are removed from their dams when 2 or 3 days old so as to develop and preserve the milking qualities of the cows. This necessitates the feeding of skim milk to the calves and . . . the best returns are made when corn meal is fed as an additional food in preference to oil meal, oatmeal, or flaxseed."

The value of wide and narrow rations was tested with 2 lots of 7 steers each (this comparison being a part of the first test reported above). The ration was made up of a number of grains and coarse fodders. From July 16, 1897, to August 1, 1898, lot 1 was fed a narrow ration, the nutritive ratio being 1:3:9, and lot 2 was fed a wide ration, the nutritive ratio being 1:7.6. The average daily gain of the steers in lot 1 was 1.93 lbs., the dry matter eaten per pound of gain 7.63 lbs., and the cost of food per pound of gain 4.02 cts. Similar

values for lot 2 were 1.91 lbs., 7.73 lbs., and 3.52 cts. After the close of this period the steers were fed until December 9, 1898, a ration with the nutritive ratio of 1:6.5. During this period the average gains of the 2 lots were 1.12 and 1.32 lbs.; the dry matter eaten per pound of gain, 20.54 and 17.43 lbs., and the cost of food per pound of gain, 9.15 and 8.92 cts., respectively.

"The results support the statement that the narrow ration is likely to give the greatest gains, while the wide ration is more favorable to cheap gains. The relative cheapness of these rations will largely depend on local conditions, whether or not the farm grains grown in the community are representative of the carbonaceous or nitrogenous foods."

In testing the possibility of profitably fattening range steers, 17 such animals were fed January 26, 1898, to April 6, 1900. During the winter corn and corn fodder were the principal feeding stuffs used, as it was desired to make the test with such foods as were generally available locally. During the summer the steers were pastured. The average daily gain per steer during the whole test was 1.35 lbs.; the cost of a pound of gain, 4.10 cts; the dry matter eaten per pound of gain was 10.19 lbs. the first winter, 11.75 lbs. in the second, and 12.96 lbs. in the third. At the conclusion of the test 3 of the steers were sold in the local market for 4.5 cts. per pound, and the remainder in Chicago for 5.45 cts. per pound. The authors compute that in this test the profit was \$8.16 per steer.

"The feeding of range steers with the application of present prices for feeders and the fattened product does not permit of securing much profit in comparison with the returns that may be secured from a herd and its products bred for the special purpose of meeting the conditions of a combination of dairying with beef making."

Steer feeding, D. O. NOURSE (*Virginia Sta. Bul.* 105, pp. 183-187).—Whole corn and corn-and-cob meal in combination with other foods were compared for a period of 4 weeks with 7 steers, each weighing about 1,200 lbs. A steer fed corn on the ear, bran, whole oats, and hay lost in this time 5 lbs. One fed corn-and-cob meal, ground oats, bran, and hay gained 78 lbs. When cotton-seed meal replaced ground oats in the ration, a third steer gained 94 lbs. With corn silage in addition to this last ration, one of the steers gained 18 lbs., and with corn stover in place of hay and silage another gained 2 lbs. With 2 steers corn-and-cob meal was the only grain fed. One received hay and the other corn stover as coarse fodder. The former gained 9 lbs. and the latter lost 53 lbs. According to the author—

"Ground corn seemed better than whole corn, especially when fed dry. A considerable variety of food seems desirable. Corn alone, as it is with other foods generally, does not give the best returns. Corn silage, as one portion of the coarse fodder, is desirable.

"The largest gain obtained was with rations containing cotton-seed meal. The only animal refusing grain at any time was one whose grain ration was composed of corn alone."

Fattening range lambs, C. F. CURTISS and J. A. CRAIG (*Iowa Sta. Bul.* 48, pp. 452-456).—In discussing the fattening of range lambs 2 trials are reported. One of these has been noted from a previous publication (*E. S. R.*, 9, p. 977). In the second trial, which included 191 lambs and covered 105 days, the average daily gain per lamb was 0.23 lb., the cost of food per pound of gain 4.3 cts., and the dry matter eaten per pound of gain 10.74 lbs. The food supplied included oats, bran, corn, oil meal, roots, hay, and corn fodder. Judged by results of the 2 experiments, the authors believe that "there are fair profits to be made from fattening range lambs under the conditions of our State."

Fattening lambs in comparison with yearlings, C. F. CURTISS and J. A. CRAIG (*Iowa Sta. Bul.* 48, pp. 457-460).—Two tests on the comparative economy of feeding lambs and yearlings are reported, the results of the first being quoted from a previous publication (*E. S. R.*, 9, p. 75). In the second test 10 lambs and 10 yearlings were fed for 91 and 70 days, respectively, oats, corn, oil meal, hay, beets, and corn fodder. The average weight of the lambs at the beginning of the trial was 90.2 lbs. and the yearlings 147.7 lbs. The average daily gain in the 2 lots was 0.29 and 0.23 lb., respectively; the cost of food per pound of gain 4.78 and 5.51 cts., and the dry matter eaten per pound of gain, 11.22 and 14.65 lbs. Both lots were sold and slaughtered. The dressed weight of the lambs was 50.7 per cent of the live weight; of the yearlings, 55.6 per cent. The authors believe these trials show the superior value of lambs. "In view of the fact that the lambs also bring a higher price on the market and they may be also marketed earlier, the selection of them for winter feeding seems to be much more preferable than to buy yearlings for this purpose."

A study of pork production from the standpoint of the farm and the market, C. F. CURTISS and J. A. CRAIG (*Iowa Sta. Bul.* 48, pp. 373-451, pl. 1, figs. 22, dgms. 2).—The work reported extended over 3 years, beginning with 1896. Data are reported on pigs and sows before weaning and on pigs alone after weaning. In these tests the comparative value of Berkshires, Poland Chinas, Chester Whites, Duroc Jerseys, Yorkshires, and Tamworths was tested, crossbred Tamworths and Yorkshires being also included in the first trial. Considering the different breeds in the order mentioned the average cost of a pound of gain in the 3-year test by the sows and pigs before weaning was 4.29, 3.15, 3.27, 5.61, 1.83, and 2.22 cts., respectively. The cost in the case of the crossbred pigs was 6.80 cts. The average cost of a pound of gain by pigs of the different breeds after weaning was 2.33, 2.23, 2.46, 2.27, 2.14, and 2.42 cts., respectively, and 2.81 cts. by the crossbred pigs (tested only 1 year). In the third trial the comparative value of wide and narrow rations was also tested with 2 lots of 5 Durocs each. The cost of food per pound of

gain on the narrow ration was 2.26 cts. and on the wide ration 2.01 cts.

The value of different breeds for dressed pork and bacon is discussed, many statistics of the export trade of pigs and the manufactured bacon being given. Considering the average cost per pound of gain before weaning, the breeds ranked as follows: Yorkshire, Tamworth, Poland China, Chester White, Berkshire, and Duroc Jersey; considering the average cost per pound of gain after weaning: Yorkshire, Poland China, Duroc Jersey, Berkshire, Tamworth, and Chester White. The Yorkshires gave the largest dressed weight in proportion to weight before slaughtering, being followed by the Poland Chinas, Tamworths, Chester Whites, and Berkshires and Duroc Jerseys in the order mentioned. As regards the total value of cuts in carcasses, the breeds ranked as follows: Yorkshire, Tamworth, Poland China, Duroc Jersey, Chester White, and Berkshire; as regards quality of meat, *i. e.*, a satisfactory mixture of fat and lean, they ranked as follows: Tamworth, Berkshire, Chester White, Duroc, Poland China, and Yorkshire. The Tamworths were considered most suitable for export trade, the Yorkshires least so, while the Berkshires, Chester Whites, Durocs, and Poland Chinas ranked next to the Tamworths, in the order mentioned.

In connection with one of the tests reported above, extended chemical studies of the composition of the flesh of the different breeds were made by the Division of Chemistry of this Department (E. S. R., 10, p. 877).

“While the testimony of these experiments is most strongly directed toward emphasizing the necessity of securing the right type of a hog as represented in the bacon breed, yet the results show that the question of feeding is one of equal importance. . . . It was very manifest that the feeding of a wide ration or one rich in carbonaceous materials resulted in a carcass excessively fat, while the feeding of a narrow ration, or one rich in nitrogenous materials, made a carcass containing more or less meat or muscle. [*i. e.*, type for bacon.]

“If a division of this industry into the raising of bacon hogs as well as the production of lard pigs is brought about, so that the 2 types are distinctly recognized in the market, it would seem very evident that it would materially help the price of the lard hog. The creating of a demand for a new product would necessarily lighten the competition in the other direction, which it is natural to suppose would result in stronger prices. Instead of desiring to check the development of bacon production it would seem the best policy for the hog breeder to try and encourage it by producing the type and feeding for the purpose of satisfying the bacon market.”

Poultry experiments (*Utah Sta. Bul.* 67, pp. 121-159, pls. 6).—Continuing previous work (E. S. R., 11, p. 480), tests are reported on the relative value of pullets and hens, early and late hatched pullets, and the effect of exercise on egg production. The feeding value of corn, dried blood, and sunflower seed as a part of the ration was also tested. The test began with 15 lots of 5 pullets or hens each and covered 1 year. The breeds used were Leghorns, Wyandottes, and Plymouth Rocks. With the exceptions noted, all the lots were fed

in the morning a mash composed of bran, ground oats, and corn, 2:1:1, seasoned with salt and cayenne pepper. Four lots, however, had dried blood added to the mash—that is, these lots were fed a ration with a narrower nutritive ratio than the other lots. Wheat and oats were fed in the middle of the forenoon on alternate days, and late in the afternoon wheat. One lot received sunflower seed in the place of wheat in the forenoon, and another lot corn in place of wheat both morning and evening. Cut bones and butchers' scraps were fed three times a week, and in the winter green food in addition. Most of the feeding stuffs were analyzed. The lots with exercise were compelled to scratch for their grain ration, which was scattered in straw. The others were fed from troughs. From these and the earlier tests the author draws a number of deductions, some of which follow:

"As to the effect of exercise on food consumption, the average . . . for 3 years shows that the pen with 'exercise' consumed 62.4 cts. worth of food, and the pen 'without exercise' 60.8. In the case of 2 other pens the average was 63.5 cts. and 62 cts., respectively, per fowl in favor of 'no exercise.'

"During the year the Leghorns consumed an average of 62 cts. worth of food per fowl. The Wyandottes consumed 81.6 cts. per fowl, and 2 pens of Plymouth Rocks averaged 87.7 cts. per fowl. The Leghorns consumed during the year an average of about 75 lbs. of total food, or about 55 lbs. of dry matter per fowl; the Wyandottes 100 lbs. total food, 73 lbs. dry matter, and the Plymouth Rocks about 110 lbs. total food, and about 80 lbs. dry matter. The 3 years' results from Leghorn pullets show an average of 162 eggs per fowl per year at a food cost of 4.6 cts. per dozen. These results are not from selected or 'pedigree' layers.

"The record of weights of fowls shows that Leghorns weigh about 10 per cent more during their second year than during the first year as pullets. During the third year there is practically no increase in weight.

"The largest egg production was during the period of greatest food consumption. The smallest egg yield was when the food consumption was least. The hens attained their greatest weight immediately preceding the periods of greatest egg production. After the periods of heavy laying they showed a loss in weight.

"Five pens of Leghorns 2 and 3 years old laid eggs averaging 1.56 lbs. per dozen. Five pens of Leghorn pullets laid eggs averaging 1.37 lbs. per dozen. The eggs from the pen of Wyandotte pullets averaged 1.56 lbs. per dozen, and those laid by 4 pens of Plymouth Rock pullets averaged 1.52 lbs. per dozen. Eggs from different hens of the same breed varied in weight. The eggs from 5 pens of Leghorn pullets averaged 1.44 lbs. per dozen. The eggs from the same pens during the second year averaged 1.54 lbs. per dozen. In other words, the size of the eggs was 8 per cent greater the second year than the first.

"A test of wheat *v.* corn gave results in favor of wheat for egg production. In the case of Leghorn pullets the addition of dried blood to the ration considerably increased the egg yield. With Plymouth Rock pullets no effect was noticed on the yearly record. With both, the pens having dried blood began laying earlier than the others. The discarding of corn (except the little used in the mash) and substituting a small quantity of sunflower seed did not materially affect the egg yield, there being but a slight increase. Owing to the greater cost of the sunflower seed, the financial results were in favor of the corn. The results of a test with Leghorn pullets showed that a nutritive ratio of 1:4.95 was much superior to one of 1:6.66. With Plymouth Rocks the results were inconclusive."

A caponizing experiment is also briefly reported. A cockerel and capon, each weighing 1.9 lbs. at the beginning of the test, were fed for about 10 months under the same conditions. The capon then weighed 7 lbs., the cockerel 6.4 lbs. Although there was little difference in weight in the two cases, the meat of the capon when cooked was regarded as of superior quality, as was also the appearance of the dressed bird.

Aspects of mental economy, M. V. O'SHEA (*Bul. Univ. Wisconsin No. 36*, pp. 33-198, figs. 18, charts 3).—As stated in the subtitle, the author discusses some phases of the dynamics of the mind and records observations on the students at the University of Wisconsin. These include the kind and amount of food consumed, statistics regarding living habits, etc. On the basis of his observations and a review of some of the literature of the subject, a number of deductions regarding the value of different foods, etc., are drawn. These are not always in harmony with the commonly accepted conclusions of physiologists and specialists in nutrition. The lack of references to the great mass of the recent scientific work on the topics discussed is noticeable.

Compendium for food chemists, A. BUJARD and E. BAIER (*Hilfsbuch für Nahrungsmittelchemiker. Berlin: J. Springer, 1900, 2. ed., pp. XVIII+454+155, figs. 8; rev. in Ztschr. Untersuch. Nahr. u. Genussmittel, 3 (1900), No. 8, pp. 590, 591*).—This edition has been revised and enlarged.

Flesh foods with methods for their chemical, microscopical, and bacteriological examination, C. A. MITCHELL (*London: Charles Griffin & Co., Ltd., 1900, pp. XI+336, pl. 1, figs. 58*).—As the subtitle explains, this book is designed as a practical handbook for physicians, analysts, inspectors, and others interested in the topics discussed. The structure and composition of flesh foods, their methods of examination and preservation, and similar topics are treated of, the author's purpose being to collect and summarize the records of the many investigations which have been reported in English and foreign publications relating to these subjects.

Air, water, and food from a sanitary standpoint, ELLEN H. RICHARDS and A. G. WOODMAN (*New York: John Wiley & Sons; London: Chapman & Hall, Ltd., 1900, pp. 226, pl. 1, figs. 10*).—In a manner designed to suit the needs of students the authors treat of such topics as air, the problem of ventilation, water—its sources and properties; water as a possible carrier of infection; food and nutrition, and food adulteration. The important analytical methods necessary for chemical analyses and examinations connected with these topics are described. Many tables useful in computing results of analyses and a somewhat extended bibliography of the subjects treated of are also included.

Chemical foods in modern times, E. EICHENGRUN (*Ztschr. Angew. Chem. 1900, No. 11, pp. 261-269*).—In an address the author discusses some of the recent food preparations, such as albumoses, peptones, malt preparations, and the like.

Certain determinations introduced in the analysis of bread, A. SCALA (*Staz. Spr. Agr. Ital., 32 (1899), pp. 489-498*).—The composition (including calculated digestibility and power to absorb water) of a number of samples of bread is reported. One of the samples was made in part and another entirely from Indian corn.

The acidity of flours, MARION and MAGNET (*Ann. Chim. Anal. et Appl., 5 (1900), p. 164; abs. in Bul. Assoc. Belge. Chim., 14 (1900), No. 5, p. 233*).—Experiments are reported and modifications of Balland's method of determining acid suggested.

The manufacture and adulteration of sausages, M. H. MARTEL (*Public Health, 12 (1900), No. 8, pp. 636-638*).—This is an abstract of an article in *La Presse Médicale*, January 24, 1900. The author describes and discusses the principal methods of adulterating sausages—i. e., (1) by the addition of antiseptic substances, of pre-

servative salts in excess, or of coloring matters; (2) by the addition of starch, flour, rice flour, and breadcrumbs; (3) by the use of flesh of animals which have died naturally or have been slaughtered on account of disease; (4) by the use of parts of animals not usually eaten (as the hides of oxen); and (5) by the use of the flesh of such animals as the dog, cat, and horse. The methods of detecting adulteration are discussed in some considerable detail.

Notes on vinegar, J. EDMUNDS (*British Food Jour.*, 2 (1900), No. 20, pp. 210-214).—Discussing malted vinegars, the author states that on account of watering and bad brewing most of them contain only about 3 per cent of acetic acid. These vinegars tend to spoil and hence manufacturers often have to resort to the addition of sulphuric acid to preserve them. A good malted vinegar should contain about 6 per cent of acetic acid, but not more than 0.01 to 0.03 per cent of sulphuric acid.—C. B. WILLIAMS.

Nutrition investigations in California, M. E. JAFFA (*U. S. Dept. Agr., Office of Experiment Stations Bul.* 84, pp. 39).—Four dietary studies of infants, one of a football team, and one of a family are reported, as well as digestion experiments with an infant and determinations of the balance of income and outgo of nitrogen. A number of foods were analyzed in connection with the studies.

Composition of *Apios tuberosa*, C. BRIGHETTI (*Staz. Sper. Agr. Ital.*, 33 (1900), pp. 72-75; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 453, II, p. 498).—Analyses of the ground nut.

The digestibility of some nonnitrogenous constituents of certain feeding stuffs, G. S. FRAPS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 9, pp. 543-553).—Noted from another report of this work. (See p. 667.)

How far is sugar to be recommended as a feeding stuff? F. LEHMANN (*Braunschweig. Landw. Ztg.*, 68 (1900), Nos. 10, pp. 39, 40; 11, pp. 46, 47; 12, pp. 51-53; 13, pp. 57-59).—A general discussion, quoting the work of a number of investigators.

Beet molasses feeding stuffs, GERLACH (*Bl. Zuckerrübenbau*, 7 (1900), No. 6, pp. 92-94).—The value of several molasses feeds is discussed.

Analyses of prickly pear, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 671-674, pl. 1).—Analyses of the leaves of different sorts of prickly pear are reported and their feeding value discussed.

Stock feeding, F. C. BURTIS (*Oklahoma Sta. Rpt.* 1900, pp. 120-131).—A general article on feeding farm animals, with tables showing the composition of common feeding stuffs.

Experimental pig feeding, J. MAHON (*Queensland Agr. Jour.*, 7 (1900), No. 1, pp. 23, 24).—Results of tests for the purpose of ascertaining the value of cane molasses when combined with other foods. Pigs fed ground barley required 5.5 lbs. for a pound of gain and those fed barley and molasses, 5.08 lbs.

Pig-feeding experiments (*Bd. Agr. [London]*, *Rpt. Agr. Education and Research*, 1890-1900, pp. 113-116).—Two pig-feeding experiments at University College, Nottingham, are briefly reported. In the first scalded maize meal was compared with raw maize meal, no advantage being found for the former method of feeding. Both lots were fed whey in addition to the maize meal. In the second test sweet and sour separator skim milk were compared; some grain, principally maize meal, being fed in addition. The conclusion was drawn that the feeding value of skim milk was not increased by souring, but, if anything, slightly diminished.

Swine feeding especially relating to the use of succulent foods, C. S. PLUMB (*Nat. Farmer and Stock Grower*, 4 (1900), No. 1, pp. 74-78).—A popular article gathered from various sources and read before the Indiana Swine Breeders' Association, January, 1900.

Fundamental principles of feeding horses for light and heavy work, J. SHIROKIKH (*Arch. Vet. Nauk., St. Petersburg*, 30 (1900), Nos. 2, II, pp. 64-87; 3, II, pp. 122-142).—A general discussion of the subject.

Trout culture for farmers, W. E. MEEHAN (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 312-323*).—Raising trout is recommended as a profitable enterprise for farmers, and directions are given.

Trade in agricultural commodities—animals for slaughter and meat products, A. DULAC (*Ann. Agron., 26 (1900), No. 9, pp. 430-472*).—A comprehensive article on the commercial side of animal husbandry, with special reference to animals bred for slaughter.

DAIRY FARMING—DAIRYING.

Corn silage, sugar beets, and mangels—a comparison of their value as dairy foods, H. J. WATERS and E. H. HESS (*Pennsylvania Sta. Rpt. 1899, pp. 111-123*).—A feeding experiment with 3 lots of 3 cows each and covering 3 thirty-day periods is reported. During the entire test all the cows were fed daily 7 lbs. of mixed grain and 6 lbs. of field-cured corn stover. During periods 1 and 3 all the cows received in addition silage, sugar beets, and mangels, each in quantities furnishing 2 lbs. of digestible dry matter. During period 2, in addition to the grain and stover, lot 1 received 6 lbs. of digestible dry matter in silage; lot 2, 6 lbs. in sugar beets; and lot 3, 6 lbs. in mangels. The results of the test showed a slight increase in the amount of butter, and percentages of fat and solids-not-fat in changing from the mixed ration of silage, sugar beets, and mangels to silage alone, and a slight decrease in changing from the mixed ration to either sugar beets or mangels alone. They are considered, however, as showing no practical difference in the effect of silage and roots upon the yield and quality of milk, but the mixture of silage and roots is considered slightly better than the same quantity of either fed separately.

A brief summary is given of previous experiments at the station along this line (E. S. R., 3, p. 718; 6, p. 446; 7, p. 976).

Rye meal and Quaker-oats feed for milk production, H. HAYWARD (*Pennsylvania Sta. Bul. 52, pp. 8*).—An experiment covering 3 periods of 35 days each was conducted with 9 cows to compare Quaker-oat feed and rye meal as feeding stuffs for milch cows. The cows were divided into 3 lots. All 3 lots during the first and third periods and 1 cow in each lot during the second period were fed a control ration made up of $2\frac{1}{2}$ lbs. of cotton-seed meal, $3\frac{1}{2}$ lbs. of corn meal, 2 lbs. of new process linseed meal, and timothy hay *ad libitum*. During the second period the corn meal was replaced, respectively, by the same quantity of Quaker-oat feed and rye meal, and these contrasted rations were each fed to 1 cow in each lot. Variations in the live weight of the animals were small. The average cost per pound of milk and fat was highest on the rye-meal ration and lowest on the corn-meal ration.

“Rye meal, fed as part of a properly balanced ration, did not materially decrease the flow of milk, but was nearly if not quite as efficient as an equal weight of corn

meal. The very slight difference observed is probably referable to the slightly greater digestibility of the corn meal.

"Quaker-oat feed, similarly fed, caused somewhat more decrease in the production of milk than did rye, but the effect was very slight and no greater than would be expected from the probably lower digestibility of the Quaker-oat feed."

The feeding value for milch cows of the solids-not-sugar in molasses, E. RAMM and C. MOMSEN (*Milch Ztg.*, 29 (1900), No. 28, pp. 433-436).—A brief summary is given of a feeding experiment previously reported (E. S. R., 9, p. 876), in which molasses proved superior to sugar. In the experiment here reported 5 cows were fed for 4 periods of 4 days each (preceded by preliminary periods) a basal ration of hay, straw, roots, and peanut meal. In addition molasses (*Restmelasse*) was fed during the first and fourth periods, raw sugar during the second period, and raw sugar and molasses distillery residue (*Melassenschlempe*) during the third period, the sugar content of the 3 rations being the same. The cows produced the most milk and the least butter fat when fed the sugar ration, and the most fat and solids when fed the sugar and molasses distillery residue. The content of fat and solids in the milk produced on the molasses ration was, respectively, 3.20 and 11.65 per cent, on the sugar ration 2.84 and 11.32 per cent, and on the sugar and molasses residue ration 3.39 and 12.06 per cent. The results are therefore considered as showing that molasses has a greater feeding value for dairy cows than sugar, and that the constituents in molasses other than sugar are especially valuable in the production of butter fat.

The composition of milk and milk products, H. D. RICHMOND (*Analyst*, 25 (1900), Sept., pp. 225-231).—Data are summarized for over 29,000 samples of milk analyzed in the laboratory of the Aylesbury Dairy Company. The average for the year was 12.67 per cent of solids and 3.74 per cent of fat; the lowest fat content occurred in June and the highest in October. The author deduces a considerable number of analyses to show that "all milks, abnormal or otherwise, conform to the following two rules, which are practically different modes of expressing the same fact: (a) The solids-not-fat, less the milk sugar, calculated on the milk devoid of fat, amount to at least 4 per cent; (b) the sum of the specific gravity degrees and the fat, less 4 times the milk sugar, exceeds 16."

Timpe's¹ view that there is a constant relation between the proteids and fat in genuine milk and his proposition to detect adulteration by a divergence from this relation are discussed at considerable length. The author takes exception to Timpe's deductions.

Tests were made of paraphenylene-diamin and metaphenylene-diamin for distinguishing between fresh and boiled milk. The latter, together with anyl alcohol, was recommended as the best reagent.

¹ Chem. Ztg., 23 (1900), p. 1040 (E. S. R., 12, p. 286).

The composition of clotted cream, the water content of butter, and analyses of 2 samples of butter made with a butter increaser are given. The latter contained over 20 per cent of water.

Milk preservatives, C. B. COCHRAN (*Pennsylvania Dept. Agr. Rpt.* 1899, pt. 1, pp. 277-289).—The author discusses the use of boric acid and formaldehyde in preserving milk and the physiological action of these antiseptics on man and the lower animals. The literature of the subject is reviewed, tests are given for the detection of boric acid and formaldehyde, and results of experiments by the author are briefly noted. The antiseptic power of formaldehyde in milk was found in experiments to be about 50 times as great as that of boric acid. No difference was observed in the artificial digestion of pure milk and milk to which formaldehyde had been added at the rate of 1 to 10,000. Formaldehyde added in large quantities (1:1,000 to 1:200) to milk at the time of renneting or 6 hours before retarded or prevented coagulation and in other respects modified the action of the rennet. Minnows and tadpoles withstood quite well a 1 to 50,000 solution of formaldehyde, remaining alive from 4 to 6 days, while they died in a few hours in a solution of corrosive sublimate of the same strength. "When we bear in mind the fact that minnows are exceedingly sensitive to most poisons and that the formaldehyde must have been present in the blood and in every tissue to the extent of 1 part in 50,000, it shows that some animal tissues, at least, stand formaldehyde very well." Microscopical paramecia showed considerable ability to withstand dilute formaldehyde for a time. The author prefers formaldehyde to boric acid as a milk and cream preservative, on the ground that it is less injurious and that "it is impossible to use formaldehyde in excessive amounts, since its presence is then betrayed by the sense of taste." Objections to the use of preservatives in milk are considered.

Investigations on the cause of the rancidity of butter, R. REINMANN (*Centbl. Bakt. u. Par., 2. Abt., 6* (1900), Nos. 5, pp. 131-139; 6, pp. 166-176; 7, pp. 209-214).—From a review of the literature on the subject and the experiments covering a variety of conditions, the author arrives at the following conclusions: (1) The amount of free acid formed in butter bears no relation to the rancid taste and odor. (2) A high content of casein and milk sugar in butter is very favorable to rancidity. (3) The oxygen of the air is not of the importance in the production of rancidity in butter which has been claimed, since sterile cream butter does not become rancid with the free access of air. (4) Light does not appear to be of any importance in this connection. (5) Under ordinary conditions butter made from sterilized cream does not become rancid. Rancidity can be induced, however, in a few days by working into it a very small quantity of rancid butter. (6) The question as to whether the rancidity of butter is due to the action of micro-organisms or ferments is still an open one.

Examinations of the chemical properties of Danish butter fat, E. HOLM and P. V. F. PETERSEN (*46. Rpt. Kgl. Vet. Landbohøjskoles Lab. Landökon. Forsög [Copenhagen], 1900, pp. 106*).—This work was extended over 4 years, 1896 to 1900, 7,834 samples of butter from about 800 creameries being examined, as well as butter from individual cows on different farms.

Examination of butter fat in Danish creamery butter.—The refractive index of all samples ranged between 48.6 and 54.9, over 80 per cent of the samples being between 51 and 52. There was practically no difference in the index of butter from different parts of Denmark, and but slight difference between that from large estates and creameries. Regular seasonal changes were observed in the refractive index, Reichert number, and iodine number. The average refractive index for 4 years, Reichert number for 3 years, and iodine number for 2 years are shown below:

Average results for Danish butter fat per month.

Month.	Refractive index.	Reichert number.	Iodine number.
April	51.0	30.1	<i>a</i> 33.4
May	51.1	30.0	<i>a</i> 35.0
June	51.1	30.4	<i>a</i> 37.1
July	51.6	30.2	<i>a</i> 38.4
August	52.1	28.8	<i>a</i> 39.0
September	52.6	27.5	41.6
October	52.8	27.5	44.0
November	51.0	29.6	36.6
December	50.2	30.7	33.0
January	50.5	30.9	<i>a</i> 33.3
February	50.6	31.0	<i>a</i> 34.5
March	50.8	30.9	<i>a</i> 34.1
Average	51.3	29.8	36.7

a One year only.

The highest values for refractive index and iodine number are coincident with the lowest Reichert numbers, a gradual increase or decrease of the latter being accompanied by a change in the opposite direction of the former. A difference of 1° in the refractive index was found to correspond to a difference of about 3 in the iodine number.

Forty-four samples of artificial butter of Danish, Swedish, Norwegian, Dutch, and German origin gave refractive indexes ranging from 57 to 61.5 $^{\circ}$, the minimum, therefore, being 2.1 $^{\circ}$ above the maximum for pure Danish butter. Mixtures of artificial and natural butter fat containing 10 to 90 per cent of the latter gave a refractive index identical with the calculated index in all cases.

The authors show that the quality of butter and its commercial value stand in no relation to its composition, and that a perfect guarantee of purity can not be established by means of chemical standards.

Examination of butter fat from individual cows.—Six cows were selected from each of 3 Danish dairy farms, 2 of each lot being fresh milkers, 2 in about the middle of their lactation periods, and 2 old

milking cows. The results of examinations of the butter, monthly, for a year showed in the case of both new and old milkers that the refractive index of the butter fat and the iodine number increased considerably when the cows were let out in the spring, and decreased when they were changed to stable feeding in the fall.

The changes in the refractive index and iodine number during the period of lactation follow each other closely, decreasing during the first 3 months after calving, to increase from that time on until the cows are dry; while the Reichert number changes but little up to the fifth month after calving, from which time on there is a steady decrease till drying-off time.

The variations in the case of individual cows are tabulated and compared with those for creamery butter. The general conclusion is drawn that variations in the chemical properties of Danish export butter are not due to adulteration, as has occasionally been claimed, but are caused by the natural variations in the butter fat from the individual cows. —F. W. WOLL.

On the biology of peptonizing milk bacteria, O. KALISCHER (*Arch. Hyg.*, 37 (1900), No. 1, pp. 30-53).—The author's investigations were made with a bacterium belonging to the group of hay or potato bacilli, which, according to Flügge, are not killed by heating milk to 90-95°. It possessed the property of curdling milk by means of a rennet-like ferment and then of dissolving the precipitate of casein by means of a peptonizing ferment. The investigations showed that its growth in milk was accompanied by a diminution in the milk sugar, which is believed to be directly connected with the life process of the bacteria. The inversion of the sugar took place entirely within the cell, and no ferment capable of inverting milk sugar was formed. The only decomposition products of the milk sugar which could be identified with certainty were volatile acids. The fat was not attacked by the bacteria, and no diastatic ferment was elaborated. The products of its action on casein were albumose and later peptone, together with ammonia, volatile fatty acids, and a number of other substances. By fermentative action alone there was produced from the casein peptone, leucin, and tyrosin, the aromatic oxy acids, and ammonia in small quantity. Except in its ability to produce oxy acids, the digestive ferment corresponded entirely to trypsin. The rennet ferment produced by the bacterium was very analogous to ordinary rennet.

Studies on the enzymes of cheese, O. JENSEN (*Ann. Agr. Suisse*, 1 (1900), No. 5, pp. 159-198).—The object was to study the enzymes found in cheese, and the rôle they play together with bacteria in the ripening processes. Limburger is taken as a representative of the soft, while Emmenthaler is chosen as a type of the hard cheeses.

The author finds 2 enzymes active in the ripening processes of the 2 cheeses, galactase of milk and pepsin of rennet. These enzymes

pass into the curd in the process of manufacture in sufficient quantity to produce transformation in the casein. The soft cheeses, by reason of the methods of their manufacture, are from the first richer in enzymes than the hard cheeses, those made by pressure.

To determine the presence of galactase the methods of Babcock and Russell were followed (E. S. R., 11, p. 578). As an antiseptic to prevent the growth of bacteria 1 per cent formalin was usually employed, but in some cases ether was used, owing to the restraining action of formalin upon the action of galactase. This action of formalin is used as a means of showing the degree of the activity of galactase in cheese ripening. Analyses of the 2 cheeses at different periods are given, showing the content of soluble nitrogen, nitrogen not precipitated by phosphotungstic acid, nitrogen in the form of ammonia, and lactic acid.

Just after making Limburger cheese contains a considerable amount of lactic acid, which favors the action of the pepsin and restrains the action of the galactase. At the beginning the ripening of Limburger cheese is due wholly to the action of the pepsin. This action is limited little by little by the action of more energetic enzymes, while the acid present is diminished by the ammonia formed. This action is naturally most active at first at the surface of the cheese, the action proceeding toward the interior. From the investigations the author concludes that the transformation of the casein during the ripening of Limburger cheese is the result of a digestive fermentation in which the surface of the cheese is the point of beginning, and that this fermentation is due to the action of yeast or bacteria aided at the outset by a digestive pepsin operating throughout the mass.

The previous work of the author on the ripening of Emmenthaler cheese has been noted (E. S. R., 11, p. 980). The ripening of this cheese is accompanied by the processes of salting and drying that in a measure restrain the different fermentations. Owing to the pressure in the manufacture this cheese contains at the beginning less lactic acid than the soft cheeses, which is perhaps favorable to the action of the galactase while in a measure restraining the action of the pepsin. From his investigations the author concludes that the transformation of the casein during the ripening of Emmenthaler is the result of a bacterial fermentation, in a degree digestive, equally distributed in the cheese and probably aided in the beginning by the action of galactase.

Variations in the fat content of the milk of individual cows, I. BOY-ESSENS (*Milch Ztg.*, 29 (1900), No. 32, pp. 501-503).—This consists of data from the records of a number of herds.

A new apparatus for the condensation of milk and other liquids, O. HENZOLD (*Milch Ztg.*, 29 (1900), No. 26, pp. 401-403, figs. 3).—The apparatus is figured and described and tests are reported. No vacuum is required.

Milk poisoning in Malta, T. ZAMMIT (*British Med. Jour.*, 1900, No. 2054, pp. 1151, 1152).

The variability of lactic acid bacteria with reference to their capacity for souring milk, N. P. SCHIERBECK (*Arch. Hyg.*, 38 (1900), No. 3, pp. 294-315).—It

was found possible by experimental means to produce a variation of the lactic acid bacteria exhibiting a very marked decrease in fermentative ability, and this variation was perpetuated without change through a long series of inoculations. The culture obtained is not regarded as a new type, since the decrease in ability to produce acid appears to be due to unavoidable conditions in the nutritive medium.

Butter making for select trade and exportation, M. E. McDONNELL (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 263-277*).—The author gives notes on the dairy industry in Europe and discusses methods of manufacture and qualities required in butter, especially that intended for shipment to foreign countries. The topics considered include the handling of milk, pasteurization of cream and skim milk, selection and use of a starter, securing uniformity in ripening, and churning, working, salting, coloring, packing, and storing butter.

The suppression of goat's milk in the manufacture of Emmenthaler cheese, R. STEINEGER (*Milch Ztg., 29 (1900), No. 31, pp. 486, 487*).—Experiments are cited as showing the inferiority of goat's milk as compared with cow's milk in the manufacture of this cheese.

VETERINARY SCIENCE AND PRACTICE.

Report of the State veterinarian, L. PEARSON (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 144-184*).—It is stated that the repressive measures adopted against glanders have resulted in the nearly complete extermination of this disease in the State. Anthrax was reported from 12 counties during the year, and animals were vaccinated against this disease on 83 different farms. The author believes that the spread of anthrax is due largely to the neglect of anthrax carcasses, which should be burned with great care. Blackleg was reported from 8 counties during the year. It is recommended that blackleg carcasses should be burned, as in the case of anthrax. Rabies occurred in 12 counties among dogs, horses, hogs, sheep, cattle, and man. Observations made on cerebro-spinal meningitis indicate that contaminated water may be favorable to the outbreak of this disease. During the year, 56,387 doses of tuberculin were sent out from the laboratory for testing dairy cows and breeding cattle in the State. Hog cholera occurred in 16 counties. The outbreaks in most instances were traceable to infected hogs shipped from the West or South. Malignant dysentery of calves may be controlled, according to the author, by the removal of cows from the infected premises 6 or 8 weeks before the calves are born. Brief notes are also presented on actinomycosis, contagious ophthalmia, and sheep scab.

Summary of the year's pathological investigations, J. A. GILRUTH (*Veterinarian, 73 (1900), No. 870, pp. 301-315*).—Brief notes are given of an outbreak of actinomycosis. The author studied a number of cases of parasitic gastritis in calves. The disease was quite general and occurred chiefly during the winter months. The symptoms were acute and watery diarrhea lasting from 14 to 28 days, and resulting in death. The disease was due to a parasitic worm (*Strongylus cervicornis*). The author believes the predisposing causes to this disease

were found in improper feeding and lack of shelter, which lowered the vitality of the animals.

Red water is reported as prevalent in certain districts, especially on dairy farms, where it was invariably associated with injudicious feeding of turnips.

The chloral hydrate treatment for milk fever is reported as giving satisfactory results in the hands of many farmers. The Schmidt treatment has been tried with still better results.

Notes are also given on the etiology and treatment of cirrhosis of the liver in cattle and sheep, septicæmia in domesticated animals, acute congestion of the kidneys in lambs, etc.

Annual report for 1899 from the principal of the Royal Veterinary College, J. McFADYEAN (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), No. 1, pp. 93-109).—The author gives brief notes on the prevalence during the year of anthrax, glanders, pleuro-pneumonia, rabies, and swine fever. Considerable work was done on tuberculosis in cattle and in sheep, 11,151 tuberculin tests in cattle having been reported during the year. The percentage of tuberculous animals was 24. Brief notes are given on the symptoms and course of tuberculosis of the udder. One case of tuberculosis in sheep is reported and the author states this is the first indubitable case among British sheep. Suspected material from this sheep was inoculated into rabbits and resulted in producing the typical lesions of tuberculosis.

The author makes a report on a new disease of the dog which was observed in various parts of southern England and is believed to be identical with the disease which was reported as very fatal to dogs in parts of Germany during the autumn of 1898. The principal symptoms of the disease were prostration and vomiting. About 75 per cent of the cases were fatal and the average duration of the disease was from 4 to 6 days. The disease is readily distinguishable from distemper by the fact that it attacks more frequently old dogs.

Brief notes are presented on sarcoptic mange of cattle, the African horse-sickness, and the curability of glanders. The last two subjects have already been referred to at greater length (*E. S. R.*, 12, p. 292).

Plasmodiophora brassicæ as a cause of tumors in animals, W. PODWYSSOTZKI (*Centbl. Bakt. u. Par.*, 1. Abt., 27 (1900), No. 3, pp. 97-101).—The author instituted experiments in hypodermic and intraperitoneal inoculations of this organism in rabbits, guinea pigs, frogs, and axolotl. Tumors of true parasitic origin were produced and the author states the results of his experiments as follows: Tumors may be produced in animals by inoculation with *Plasmodiophora brassicæ*. The tumors are of mesodermal origin and arise as the result of a hypertrophy and proliferation of the thick connective tissue. Spores of this organism are formed in the cells of the tumors either singly or in large numbers. The spores are present in larger numbers in the

older tumor cells than in those of more recent origin. The nucleus of the cells which are filled with spores is rich in chromatin considerably enlarged and shows a decided proliferation. In some of the spores a progressive metamorphosis of their nuclear substance occurs, as the result of which 2 or 3 nuclei appear in the place of one. In the tumors produced by *Plasmodiophora brassicae*, the phagocytosis which was caused by the presence of the organism seemed always sufficient to bring about the ultimate destruction of all the parasites.

White scour in calves (*Farmers' Gaz.*, 59 (1900), No. 3, p. 50).—Ten cows were divided into 2 lots of 5 each. In lot A the cows were fed in the ordinary way, but the calves, as soon as born, were put in a clean house, and fed 4 times a day a small quantity of new milk with a little warm water in it. Each calf was fed separately, and after 3 weeks received a little separated milk and barley meal. In lot B the cows were fed for about a month before calving on 10 lbs. of bran and meal mixed in the morning and evening. The milk from these cows was given to their own calves, each calf being fed 3 times a day for a fortnight. After this period they were fed twice a day on fresh milk mixed with separated milk and barley meal.

The results of these experiments indicate conclusively the importance of careful feeding of calves and constant attention to cleanliness. No calves died from lot A while 2 died out of lot B, and of 14 calves treated in the ordinary way, 9 died.

A report on tuberculosis of cattle, L. PEARSON and M. P. RAVENEL (*Pennsylvania Dept. Agr. Rpt. 1899, pt. 1, pp. 323-533*).—The authors present a general historical account of the development of knowledge concerning this disease, together with a discussion of the means and extent of distribution, prevalence, importance, and methods for controlling this disease. From numerous tests made by the Pennsylvania Live Stock Sanitary Board, 12.2 per cent of cattle in the State reacted to tuberculin.

Experiments were conducted with guinea pigs which were kept in a compartment in the lower end of nosebags attached to tuberculous cows. The guinea pigs were thus forced to breath the air expired by the tuberculous animals. Twelve guinea pigs were used in these experiments, and were exposed for periods varying from $2\frac{1}{2}$ to 26 hours. None of them became infected. Two lots of guinea pigs inoculated with tuberculosis were kept in light and dark boxes, respectively. One lot was placed in a box with a glass front and the top and back made of wire netting covered with white cloth. The other lot was placed in a box of equal size made of wood painted black inside and a wire netting back covered with black cloth. The guinea pigs in the light box lived from $5\frac{1}{2}$ to 6 days longer than those in the black box. This experiment indicates the effect of light in checking the development of tuberculosis.

Experiments were made upon 3 tuberculous cows well fed upon a wide ration, with the result that all 3 cows improved noticeably in condition for a period of a year before yielding to the general progress of the disease.

The authors discuss the problem of checking tuberculosis by good conditions of life and sanitation, the relation of bovine tuberculosis to public health, the disposition of the flesh of tuberculous animals, the pathological anatomy and bacteriology of tuberculosis, the nature of tuberculin, the symptoms of tuberculosis, the value of the tuberculin test, and the measures adopted in different countries for the suppression of this disease. An account is given of the regulations of the State sanitary board for the control of tuberculosis. Detailed reports are given from herd owners on losses from tuberculosis and on the condition of inspected herds.

The danger of spreading tuberculosis by means of milk, and regulations for preventing this danger, KÜHNAN (*Berlin. Tierärztl. Wehnschr.*, 1900, No. 5, pp. 49-52).—This article contains a critical review of the literature upon the subject of tubercle bacilli in cows milk. The commission of the German Dairy Union has recently adopted resolutions, which are in the nature of a proposed bill, providing that all milch cows are to be inspected with reference to the presence of tubercle bacilli in their milk. The milk of suspected cows before being used must be heated to a temperature of 85° C. Every cow which is found suffering from tuberculosis of the udder is to be destroyed, and indemnity is provided ranging from \$12 to \$75.

Experimental researches on symptomatic anthrax, E. LECLAIRCHE and H. VALLÉE (*Ann. Inst. Pasteur*, 14 (1900), No. 4, pp. 202-223).—The authors give a brief critical review of the literature relating to the micro-organism of symptomatic anthrax and discuss the biology of this organism. The organism is strictly anaerobic, and it is difficult to obtain pure cultures. The organism of symptomatic anthrax produces a toxin which is capable in itself of producing serious lesions and death. The pure spores when deprived of the toxin are unable to germinate or produce an infection even when introduced into the tissues in large doses. The resistance of the organism to symptomatic anthrax depends upon phagocytic action. All conditions which prevent or hinder phagocytosis are favorable to infection.

Experiments in the treatment of infectious mammitis of cows, E. ZSCHOKKE (*Landw. Jahrb. Schweiz*, 14 (1900), No. 2, pp. 56-62).—The author presents tables showing the percentage of infectious mammitis as determined by the examination of milk samples, from 1894 to 1899. Tables show that the disease has become more frequent from year to year. It is most common during the summer months, or during the time when the greatest yield of milk is obtained. The disease appears as an enzootic or epizootic. From 2 to 4 animals became infected one

after the other in each of 4 different localities. In some cases the micro-organisms occurred in short chains or masses, while in others they were in long chains. These are believed to be mere forms of one species of streptococcus. Inoculations of 20 cc. of fresh milk from a cow suffering from infectious mammitis were made into the udder of 2 healthy cows and 2 goats. One of the cows and one of the goats developed the disease in the ordinary period of from 3 to 5 days. The other goat proved to be immune, while the second cow gave signs of the disease after a period of 2 weeks. Therapeutic experiments were tried on a pregnant cow, which was infected in 3 quarters of the udder with this disease. The green fodder which the animal had recently received was replaced with hay. After a period of 20 days the milk of this animal became clear and there was less sediment, and one week later the streptococci entirely disappeared from the udder. The animal had recovered without treatment. Experiments in injecting iodid of potash 1:1,000 parts and itrol 1:4,000 parts in lukewarm water into the infected quarter of the udder after milking were without effect in destroying the micro-organisms. The same was true where antistreptococcus serum was tried, up to 30 gm. per day for 4 days.

The colloidal silver preparation also had no effect in curing the mammitis, 50 gm. of this substance in a 1 per cent aqueous solution being injected into the jugular vein. Better results were obtained by the use of citrate of silver in the form of a salve containing 2 parts citrate of silver, 10 parts of camphor, and 88 parts of oil. This salve was thoroughly rubbed into the skin of the udder for a period of 8 days in the case of a cow infected with mammitis in all 4 quarters. The milk gradually became clearer and the number of streptococci diminished until the milk was found to be normal at the end of 16 days. Experiments with a salve containing cantharides indicated that this substance when thoroughly rubbed upon the skin of the udder produced a cure, or decided improvement, in every case. The secretion of milk, however, was much diminished, and either ceased entirely or remained much below the normal. It was found that even when all possible antiseptic precautions were observed the disease was spread by drawing milk from an infected quarter of the udder and that the other quarters of the same udder, or the udders of other cows, were more apt to become infected than when the milk from infected udders was not drawn. Accordingly it is recommended to cease milking parts of the udder affected as soon as the disease is discovered.

Stomach worms in sheep, J. F. HICKMAN (*Ohio Sta. Bul.* 117, pp. 197-212, figs. 2).—Rather serious losses of sheep have been experienced in Ohio since 1896 from attacks of a stomach worm (*Strongylus contortus*). The author gives a brief description of the worm and an account of the method of infection, the symptoms, and the forms of treatment which have already been recommended for this parasite.

Experiments with the turpentine remedy were not satisfactory, and in the summer of 1898 the author began experiments with the benzine treatment as recommended by Prof. C. Julien. Gasoline was substituted for benzine as being more conveniently purchased. One tablespoonful of common gasoline was emulsified in about 4 oz. of flaxseed tea and given as a drench to each lamb. This treatment seemed to check the trouble, and no deaths occurred after the treatment was begun. In applying this method the lambs were housed in the evening and kept with nothing to eat until 10 o'clock the following day. The gasoline was then administered and the lambs kept without food or drink for 3 hours longer. This treatment was given for 3 days in succession, and after an interval of a week the same 3 days' treatment was repeated. If improvement is not noticed in all the flock, the third treatment should be given after an interval of 10 days.

In the spring of 1899 the station began an experiment to determine the method of infection by this worm. A number of lambs of different breeds were divided into 2 equal lots, lot 1 being kept in after reaching the age of 1 month, and lot 2 allowed to feed on the pasture with the ewes. In lot 2, 7 lambs died and all of them were given the gasoline treatment. Lot 1 was kept in until the middle of September, when they were allowed to pasture on a patch of rape. No deaths occurred in this lot.

The feed for lot 1 up to September 20 cost about $14\frac{1}{3}$ cts. per head more than for lot 2, but 7 head of lambs were lost from lot 2, so that the estimated cost of each lamb up to September 5 was 65 cts. in lot 1, and 91 cts. in lot 2. The gain in weight was greater in lot 2 than in lot 1, the difference varying from 3 to 5 lbs.

The labor involved in keeping the lambs housed is perhaps the greatest objection to this method of preventing infection, but this difficulty would be partly removed by having rape for early pasture for these lambs, and by turning them on second crop clover.

Certain difficulties have been experienced by some sheep men in administering the gasoline treatment, but the author thinks these difficulties can be largely avoided by setting the sheep on its rump before giving the drench.

In the experiments carried on by the station, 1,000 doses of gasoline were given with the drench bottle with the loss of but one sheep. The condition and behavior of sheep subsequent to treatment with gasoline indicates that this method does not injure the digestive system.

The action of desiccation and heat on sheep-pox virus, L. DUCLERT and A. CONTE (*Ann. École Nat. Agr. Montpellier*, 11 (1899-1900), pp. 141-154).—During experiments conducted by the authors it was found that desiccated sheep-pox virus preserved for 14 hours at the freezing point did not lose its virulence. Previous experiments had shown that a temperature of 25° C. was most favorable for

producing a gradual modification of the virulence of this virus. Desiccated sheep-pox virus was subjected to this temperature for periods varying from 14 to 24 days. The inoculation of experimental animals was performed each day during the time that the virus was exposed to this temperature. A gradual diminution in virulence was noticed after the sixteenth day. A temperature of 30° C. was found to produce a too rapid and irregular modification of the virulence.

A diagnostic lesion in rabies, J. A. GILRUTH (*Veterinarian*, 73 (1900), No. 870, pp. 315-319).—The lesions heretofore described as diagnostic of rabies, such as vascular lesions, pigmentary atrophy, rabic tubercles of Babes, and the cellular lesions of Golgi, are considered unreliable. Peculiar lesions have been discovered in the peripheral, cerebro-spinal, and sympathetic ganglia which are regarded as specific in character. The action of the rabies virus is made manifest by proliferation of the cells of the endothelial capsule, which causes a destruction of a number of nerve cells. It is stated that the comparison of a section of a normal spinal ganglion of the dog with a similar one taken from an animal dead of rabies renders the diagnosis extremely easy.

An outline of a law regulating the slaughter of animals and inspection of meat (*Arch. Dent. Landw. Ruths*, 24 (1900), pp. 45-58).—A report on the discussion of this subject at the twenty-eighth meeting of the German Agricultural Commission.

Remarks on plague in the lower animals, F. G. CLEMON (*British Med. Jour.*, 1900, Nos. 2054, pp. 1141-1146; 2055, pp. 1216-1219).—The author gives detailed notes on the occurrence of plague in a large variety of animals, among which mention may be made of monkeys, rats, mice, squirrels, guinea pigs, marmots, rabbits, dogs, cats, horses, sheep, goats, pigs, cattle, vultures, etc. Rats may become infected with this disease from the soil, grain, flesh of other animals, rags, and insects.

An experiment in the transmission of syphilis to two calves, M. P. RAVENEL (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 5, pp. 264-268).—Two experiments were made upon calves, during which syphilitic material was rubbed into scarifications of the skin. The subsequent history of these cases indicated clearly that the disease was not transmitted to the calves. Both calves were tuberculous, and this may be of significance from the known fact of the especial susceptibility of tuberculous human patients.

An outbreak of tuberculosis among cattle at an altitude of 7,000 feet, S. W. McCURE (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 7, p. 410).—Five years previous to the outbreak of tuberculosis on this ranch, a Jersey bull had been imported from an eastern breeder. The bull later developed symptoms of tuberculosis and died. Three other cattle belonging to the herd died with the same symptoms. On investigation by the author, 5 other animals were found to be tuberculous and were killed and examined. These cattle had not been in a stable, but were allowed to range freely under conditions which would seem to be exceedingly unfavorable for the development of tuberculosis.

Tuberculosis of the udder in cows, A. BERGSTRAND (*Landtmanuen*, 11 (1900), No. 27, pp. 445-448).—This is a detailed discussion of the results obtained by Kühnan in his investigations on this disease.

Tuberculosis of the udder, H. LERMAT (*Jour. Agric. [Paris]*, 11 (1900), No. 126, p. 161).—Brief statistical notes on the prevalence of mammary tuberculosis.

Note on examination of milk for tubercle bacilli, E. W. HAMMOND (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 7, p. 395).—The author dilutes milk which is to be examined with an equal quantity of water. It is then centrifugalized for about half an hour by means of an electric centrifuge. The sediment is then removed with a fine pipette and a drop of this substance placed on a clean cover glass, dried, and finally stained by the ordinary method: As a result of diluting milk with an equal quantity of water, so little fatty material is thrown down in the sediment that it is unnecessary to use ether or other reagents to dissolve out the fat.

Tuberculin investigations (*Landtmannen*, 11 (1900), No. 25, pp. 402-405).—A summary of the results from tuberculin injections with notes on the tuberculin problem in different parts of Sweden. Rather conclusive evidence is obtained in 1 case of the transmission of tuberculosis from man to animals.

The most important tuberculins; their preparation and differences, BAUER-MEISTER (*Arch. Wiss. u. Prakt. Thierh.*, 26 (1900), No. 4-5, pp. 301-324).—The author gives a detailed discussion of the different methods of preparation and different composition of about 30 kinds of tuberculin. Some tuberculins contain certain constituents of the media upon which the tubercle bacilli were grown while other tuberculins are so prepared as to exclude all substances except the immediate products of the tubercle bacillus.

Measures to be adopted against outbreaks of anthrax in summer, W. W. FLACH (*Landtmannen*, 11 (1900), No. 20, pp. 309-315).—A general account of the means of transmission of anthrax, together with a discussion of the sanitary measures which should be adopted to prevent the spread of this disease.

Means of preventing Texas fever, L. L. LEWIS (*Oklahoma Sta. Rpt.* 1900, pp. 26-28).—Popular notes on the etiology and methods of treatment for this disease.

Blackleg: Its nature, cause, and prevention, A. T. PETERS (*Nebraska Sta. Bul.* 65, pp. 107-132, figs. 8).—This bulletin contains a popular discussion of the general subject of blackleg, including the symptoms and etiology of the disease, and detailed directions for making preventive vaccinations against blackleg.

A comparative study of the bacillus of malignant œdema and of blackleg, E. LECLAINCHE and H. VALLÉE (*Ann. Inst. Pasteur*, 14 (1900), No. 9, pp. 590-596).—From inoculation experiments with these micro-organisms, the authors conclude that there is a close biological connection between the two. The organisms may be differentiated by the fact that in the serous fluid of specific œdema, in the peritoneum of the guinea pig, the bacillus of malignant œdema appears in the long forms which are regularly absent in the case of the bacillus of blackleg. The methods of immunization which are applicable to blackleg may also be used against malignant œdema. Immunization of an animal against blackleg does not imply an added resistance to the bacillus of malignant œdema.

Pneumomycosis due to *Aspergillus fumigatus*, L. PEARSON and M. P. RAVENEL (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 8, pp. 451-465, figs. 4).—The authors give a critical review of the literature of this subject, together with notes on the cultivation and description of the mold. A Jersey cow after giving evidence of a diseased condition for a period of 6 months died, and upon examination the lungs were found to contain large quantities of the hyphæ and fruiting heads of *Aspergillus fumigatus*. The lung most affected was exceedingly emphysematous and gave a crackling sound on being rubbed. The cow did not react to the tuberculin test which was given some time before death, but upon post-mortem examination 4 or 5 caseous calcareous nodules were found in which the tubercle bacillus was present. It is suggested that the infection by the mold may have interfered with the tuberculin test.

On carcinoma in cattle, L. LOEB and G. JOBSON (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 7, pp. 385-394).—In the 2,514,446 head of cattle received at the Chicago Stock Yards during the year 1899 49 cases of carcinoma were found. In all

60 cases of carcinoma were examined by the authors, of which 59 were in cows and only one was in a steer. One of the most frequent locations for the beginning of carcinoma in cattle is in the eyelid in cases where foreign bodies enter the conjunctival sac through the running of the tear fluid and the motion of the nictitating membrane of the eye. In the study of these cases the authors noted a constant absence of metastasis in the deep lymph glands and other organs.

Sorghum as stock food, W. THOMPSON (*West Virginia Farm Rev.*, 8 (1900), No. 9, pp. 287, 288).—This article is reprinted from the *Louisiana Planter*. The author relates the circumstances of loss of stock from eating sorghum on his own estate, and suggests that the explanation of fatal results from eating sorghum is not to be found in poisonous principles, but rather in the sticky nature of sorghum leaves, which causes them to adhere to the larynx, thus strangling the animals.

The susceptibility of camels to rinderpest, TARTAKOWSKY (*Arch. Sci. Biol. [St. Petersburg]*, 8 (1900), No. 1, pp. 11-36).—Numerous experiments by the author indicate that while rinderpest assumes a mild form in the camel, the disease may, nevertheless, be carried by such animals and they should be included in quarantine regulations for the prevention of rinderpest.

Hog cholera, L. L. LEWIS (*Oklahoma Sta. Rpt.* 1900, pp. 29-32).—Brief notes on the causes, symptoms, and treatment of this disease.

Swine fever, A. H. CORY (*Queensland Agr. Jour.*, 7 (1900), No. 3, pp. 279-281).—The author describes the chief symptoms of various infectious swine diseases, of which swine fever, swine erysipelas, and swine plague are the most important.

Some difficulties associated with the eradication of swine fever, E. PEACEY (*Jour. Comp. Path. and Ther.*, 13 (1900), No. 3, pp. 236-239).—Notes on methods for diagnosing this disease and for distinguishing it from swine erysipelas and from necrotic pneumonia of swine. These 3 diseases are considered by the author to be the epizootic diseases of the pig.

Second contribution to the study of the morphology of *Bacillus mallei*, B. ALLERIO (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 12-13, pp. 353-359, figs. 26).—The author describes in detail the various forms assumed by the glanders bacillus when grown upon different cultural media. White mice have been quite generally stated to be refractory to glanders. Inoculation experiments by the author on white, gray, and black mice resulted in the death of the white mice after 18 days with numerous small glanderous tubercles. The black and gray mice did not become infected.

Hydrophobia, C. W. EDDY (*Agr. Student*, 6 (1900), No. 8, pp. 158, 159).—A discussion of the symptoms of rabies, especially in the dog, with notes on the mortality of this disease.

The rapid diagnosis of rabies, M. P. RAVENEL and D. J. MCCARTHY (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 7, pp. 404-406).—The authors examined the spinal cord, medulla, and intervertebral ganglia in 6 cases of rabies which were submitted for diagnosis. Two of the cases were dogs and 4 rabbits. The tissues were sectioned for the most part without embedding, although celloidin was used in some cases. In all cases constant changes were noted in the intervertebral ganglia. The ganglia from rabbits showed the most advanced changes. In both dogs distinct changes were produced in the cells of these ganglia and their capsules. The medulla of all cases were examined for the rabic tubercles of Babes. These tubercles were present in 5 out of 6 cases, but the method is not considered so practical for rapid diagnosis as the other just described.

Antirabies vaccination in St. Petersburg, V. KRAIOUCHKINE (*Arch. Sci. Biol. [St. Petersburg]*, 8 (1900), No. 1, pp. 96-101).

TECHNOLOGY.

Studies on cider (*Semaine Agr.*, 20 (1900), No. 1004, p. 255).—A brief review is here given of a report by L. Seguin and F. Pailhert of investigations on the comparative value of diffusion and of grinding and pressure for cider-making at the National School of Agriculture at Rennes. The results secured in these trials are summed up as follows: (1) By diffusion as concentrated a must can be obtained as the pure juice of the apple; (2) cider obtained from the same lot of apples is of equal value, whether made from juice obtained by diffusion or by pressure; and (3) fermentation takes place with equal rapidity in apple musts of equal density, whether obtained by diffusion or by pressure.

From analysis it was found that maceration increased the yield, and also the sugar, acidity, mucilage, and the ash in the musts and diminished the tannin in solution. "If the pulps are exposed for a long time to the air or frequently shoveled over, the tannin disappears and the musts are nearly colorless."

Investigations into the manufacture of cider, F. J. LLOYD (*Bd. Agr. [London], Rpt. Agr. Education and Research, 1899-1900, pp. 133-136*).—The specific gravity, solids, and acids of 64 samples of fresh juice from the press examined during 7 years (1893-1899) are reported, and accounts are given of the successful use of thin cloths in the presses; the injury to cider by the evolution of hydrogen sulphid in casks which had been sulphured, or "matched," previous to use; an examination of early-made juice which showed that it does not contain anything which should prevent the production of good cider, in spite of the tradition that early-made cider is never good; a trial of selected yeasts which showed that "a far better cider can be produced by the employment of a selected yeast than by the uncontrolled miscellaneous fermentation which is now mainly relied upon to produce cider;" and an investigation of "oily" cider which indicated that this trouble, like ropiness in milk, is due to a living organism, the nature of which was not determined. Mixing oily cider with pomace and repressing was apparently effective in correcting the defect.

Wines and wine making, A. G. FORD (*Oklahoma Sta. Rpt. 1900, pp. 76-83*).—This article discusses the principles of wine making, describes the methods in common use, and reports analyses of 17 samples of Oklahoma wines, analyses of 7 of these samples being repeated at the end of a year to determine the changes which had taken place. It was found that at the end of the year there was a slight decrease in alcohol and an increase in acids and solids.

The practical recommendations made are as follows: "Everything about the winery should be kept perfectly clean; only sound, ripe grapes should be used; the temperature during fermentation should be kept between 75 and 85° F.; the wines should be racked until no further sediment is deposited."

Theoretical and practical treatise on the manufacture of beet sugar, P. HORSINDÉON (*Traité théorique et pratique de la fabrication du sucre de betterave*. Paris: E. Bernard & Co., 1900, 2. ed., vols. 2, pp. XI+1092, pls. 5, figs. 207).

Cane sugar, W. L. BASS (New York: W. L. Bass, 1900; pt. 1, pp. 47, figs. 5; pt. 2, pp. 52, figs. 19; pt. 7, pp. 36, figs. 2; pt. 10, pp. 23, fig. 1).—Contents: pt. 1, Defecation and elimination; pt. 2, Transportation; pt. 7, Scum and by-products; pt. 10, Bagging and handling.

Rational fermentations (vinegar, cider, hydromel, alcohol), G. JACQUEMIN (*Les fermentations rationnelles (vins, cidres, hydromels, alcools)*. Malzéville—Nancy: E. Thomas, 1900, pp. VII + 878, pls. 20, figs. 57).

Cotton-plant by-products (*Tradesman*, 44 (1900), No. 7, p. 60).—Discusses briefly the proposed utilization of cotton hulls for paper making and a process for removing gum from the oil, thus giving it quick-drying properties and fitting it for use as a substitute for linseed oil.

On the peat industry, H. STEINMETZ (*K. Landtbr. Akad. Handl. Tidskr.*, 39 (1900), No. 2, pp. 109–111).

AGRICULTURAL ENGINEERING.

Wells and windmills in Nebraska, E. H. BARBOUR (*Water Supply and Irrigation Papers, U. S. Geol. Survey, No. 29, pp. 85, pls. 27, figs. 25*).—In addition to an account of homemade windmills and other water lifts which have already been reported on in a bulletin of the Nebraska Station (E. S. R., 11, p. 896) this bulletin discusses the importance of the water resources of Nebraska; the action of water underground, including sheet water, artesian water, conservation of soil moisture, pollution of water, surface and seepage water, and fluctuations of water level; methods of raising water in general; precipitation in Nebraska; surface water available for irrigation; supply for towns and cities; salt water; and blowing wells.

“The subject-matter of this paper is related to water conservation in the small way. Throughout the Great Plains region the supply of water is so scanty and so widely disseminated that as a rule it will be impracticable to provide great storage reservoirs or other works of considerable magnitude. On the other hand, for the utilization of the resources there must be innumerable attempts to employ the small amount of water almost everywhere available; and this can be done most economically through the use of the ever present force of the wind. Thus windmills throughout at least one-fourth of the United States must ever be inseparably connected with the utilization of wells and with the development of the country.”

Water resources of the Lower Peninsula of Michigan, A. C. LANE (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 30, pp. 97, pls. 7, figs. 14*).—“This material is a portion of the outcome of Dr. Lane’s studies in connection with the geological survey of the State of Michigan, supplemented by statements received in reply to circulars sent throughout the Lower Peninsula of Michigan to well drillers and others likely to be well-informed and interested in the subject. The facts thus gathered have been collated with the result of 2 months’ field work during the autumn of 1897.” Only the general conclusions from this work are presented in this bulletin, detailed data

regarding analyses and descriptions of the supply at different places being omitted. The report discusses the uses of the waters of this region for navigation, transportation, power, and domestic and technical purposes, as well as the climate of the region and its superficial geology and topography, and deeper wells and Paleozoic stratigraphy.

Barns, D. O. NOURSE (*Virginia Sta. Bul. 106, pp. 191-208, pls. 4, figs. 2*).—The specifications of a wooden hillside barn erected at the station at a cost of between \$6,000 and \$7,000 are given in full and the plans are briefly discussed. The main features of the barn are a hay and grain barn facing north, back of which are box stalls with storage space above, silos at the ends, and 2 wings with stalls for stock, running north and south, and partly inclosing an open court.

"The hay and grain barn, 40 by 100 ft. in size, faces the north, and loads may be taken in at this side and on the second floor. By this means all grain, as corn, oats, mill feed, etc., may be conveyed to bins at the left, and run by chutes to the mixing and feed room below.

"Over these bins is a large space, in which hay or fodder may be kept. At the right, on entering the driveway, is a space 40 by 42 ft., and extending from 12 ft. below driveway to comb of roof 30 ft. above it. This can be conveniently divided into 9 spaces for various kinds of hay, to be fed to classes of animals as desired. All hay is unloaded from wagons by hay carrier. . . . While unloading, the wagon stands on a set of five-ton hay scales, offering an easy opportunity for weighing all hay and grain products. Close by the cribs is a corn mill, and the meal, as it is ground, drops to the feed room below. . . .

"Beneath the driveway will be placed a gasoline engine to run the machines mentioned, besides the silage cutters, etc. The walls of the engine room are to be of metal, except the back, which will be the foundation wall. . . .

"At the eastern end of the lower floor is situated an office. . . . Next that is a herdsman's room. . . . In the rear of this room is an apartment set off for keeping the supplies needed about the barn—shovels, forks, sacks, oil, rope, etc.

"Leaving the hay barn downstairs, we step into a long feeding passage in front of the box stalls. Of these there are 10, each 9 by 10 ft. in size, arranged with a small door leading to the passage in front, and most of them with doors outward to the open court. These are used for bulls, farrowing cows, and young calves. Above the passage mentioned is a long room, 10 by 80 ft., entered by a door from the driveway above, that will be used for various purposes, mainly for the keeping of rough foders used in experiment work."

Of the 2 wings opening out of the feeding passage the west is arranged for 12 horses, 24 head of young heifers and bulls, and 40 steers; the east is arranged to accommodate 52 milch cows. Special precautions were taken to provide an abundance of light and air in these wings.

"They are 10 ft. from the floor to the plate behind the cattle, 18 ft. 6 in. to the plate over the animals' heads, and 23 ft. 6 in. to the comb of roof. . . .

"The center over feeding floor runs up with vertical sides above the roof over the cattle. By this means we get windows that swing on pins in the center of sash, that may be opened for ventilation. By a series of cords that run through sash pulleys, these windows may be partly or fully opened, and all on one side at once. These, with the ventilators on the top of the wings, windows in rear of the animals, and the

many doors, offer ample means for obtaining fresh air, and at the same time, all odors of the cattle are kept from the feed. The floors under the cattle are of 2-in. oak, laid with lead joints, making them water tight. The manure gutters are 18 in. wide, 6 in. below the floors on which the cattle stand, and 4 in. below the floor in their rear. Length of floor for stock depends on size, from 4 ft. for yearlings, $4\frac{1}{2}$ ft. for mature Jerseys, to 5 ft. for heavy steers. Feeding floor in front of all is 9 ft. wide. Various means for confining the animals are used for illustrative purposes. . . .

"Connected with the east wing, where the dairy cattle stand, is a small room to receive the milk, prior to taking it to the creamery. It is fitted with a sink and water supply, scales for weighing milk, bottle rack for samples of milk used in testing, etc. In rear of all animals the sides of the building are all ceiled and painted. . . . The stables are fitted with four manure carriers."

Connected with each end of the feeding passage is a circular wooden silo of somewhat over 200 tons capacity, resting on a rock foundation and having an earth floor. These silos were constructed with a special view to making the sides air-tight. In each silo there are three 2 by 4 ft. doors opening into a chute connected with the feeding passage.

Ample protection against fire is provided by fire hydrants and hose in different parts of the barn.

Agricultural hydraulics, Vol. III, P. L. SALVADOR (*Hydraulique agricole. Paris: Eec. C. Dunod, 1900, Vol. III, pts. 4-8, pp. VIII+563, figs. 279*).—This is one of the volumes of the *Bibliothèque du conducteur de travaux publics*, published under the auspices of the ministers of public works, agriculture, public instruction, commerce and industry, interior, colonies, and justice, of France, and discusses, in their engineering, agricultural, and legal aspects, sanitation and reclamation of swampy lands; warping; reclaiming of soils beneath the level of the sea (polders); drainage of the soil; and agricultural utilization of sewage. In the treatment of each subject the general principles and conditions are discussed and notable examples of work in the particular lines are described. The various laws of France relating to the subjects treated are given. The book is a valuable compendium of information both for the engineer and agriculturist, but its usefulness as a book of reference is seriously impaired by lack of an index.

Rating the current meter, C. T. JOHNSTON (*Wyoming Ind. Jour., 2 (1900), No. 1, pp. 10, fig. 1*).—A brief account is given of the apparatus and methods used at Cheyenne, Wyo., in testing the meters employed in the irrigation investigations of this Department.

Lifting water by compressed air, C. HOWELL (*Tradesman, 44 (1900), No. 6, pp. 89, 90, figs. 3*).—This is an account taken from the *Metal Worker* of the successful use of compressed air in pumping water for city purposes.

The limited water supply of the arid region, F. H. NEWELL (*Nat. Geogr. Mag., 11 (1900), No. 11, pp. 438-443*).—In this article the importance of storing water is shown, but it is claimed that the number of places where the conditions are suitable for the construction of storage reservoirs is limited, and that such enterprises are expensive and as a rule afford little opportunity for private profit.

Water rights according to the explanations of the civil department of cassation of the senate, D. FLEXOR (*St. Petersburg: Min. Agr. and Imp. Domains, Division of Land Amelioration, 2. ed., pp. XII+151*).

On the influence of plant cover on the flow of streams, E. WOLLNY (*Vrtljschr. Bayer. Landw. Rath., 5 (1900), No. 3, pp. 389-445*).—A discussion, based on observations by the author, of the influence of plant cover, especially forests, in mitigating floods and droughts.

Reasons for irrigation investigations and forest preservation, E. S. NETTLETON (*Wyoming Ind. Jour.*, 2 (1900), No. 6, pp. 145, 146).

The evolution of the plow, F. W. TAYLOR (*Agr. Student*, 7 (1900), No. 1, pp. 14, 15).—An abstract of a thesis presented to the faculty of the Ohio State University in 1900.

The evolution and comparison of reaping machines, M. F. MILLER (*Agr. Student*, 7 (1900), No. 1, pp. 9-11).—An abstract of a thesis presented to the faculty of the Ohio State University in 1900.

Common roads, J. D. HARPER (*Industrialist*, 27 (1900), No. 5, pp. 52-56, figs. 6).—A brief nontechnical article on the construction and maintenance of dirt roads.

Road improvement in New York (*U. S. Dept. Agr., Office of Public Road Inquiries Circ.* 35, pp. 15).—This circular gives the text of the New York road law approved March 24, 1898, with explanations of its provisions and practical operation by W. W. Armstrong.

The application of acetylene illumination to country homes, G. G. POND (*Pennsylvania Dept. Agr. Bul.* 57, pp. 85, pls. 2, figs. 5).—This bulletin deals with the history, manufacture, properties, and impurities of acetylene, and describes the various appliances employed in its preparation and utilization. A bibliography is given which consists of a "limited list of references, excluding all works in languages other than English and entering only to a very slight extent into the less popular periodicals."

STATISTICS—MISCELLANEOUS.

Annual Report of Oklahoma Station, 1900 (*Oklahoma Sta. Rpt.* 1900, pp. 11-141).—This includes a report of the director on the work, publications, and staff of the station; a paper on the work of the experiment station, by J. Fields; a summary of a large number of press bulletins issued by the station; a number of articles noted elsewhere; a financial statement for the fiscal year ended June 30, 1900; and a list of the publications issued since the organization of the station.

Annual Report of Pennsylvania Station, 1899 (*Pennsylvania Sta. Rpt.* 1899, pp. 343).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1899, a report of the director summarizing briefly the work of the station during the year, several articles noted elsewhere, lists of exchanges and available station publications, and reprints or more detailed accounts, including full experimental data of work reported in Bulletins 44-52 of the station under the following headings: Commercial butter cultures (E. S. R., 11, p. 83); heated milk for butter making (E. S. R., 11, p. 84); variety tests of wheat (E. S. R., 11, p. 731); tests of the sugar beet in Pennsylvania (E. S. R., 12, p. 44); winter v. spring bran (E. S. R., 12, p. 71); field experiments with fertilizers on tobacco (E. S. R., 12, p. 339); distillery waste, miscellaneous cattle-food analyses (E. S. R., 12, p. 378); small fruits in 1899 (E. S. R., 12, p. 645); and rye-meal and Quaker oats feed for milk production (E. S. R., 12, p. 678).

Fifth Annual Report of Pennsylvania Department of Agriculture, 1899 (*Pennsylvania Dept. Agr. Rpt.* 1899, pt. 1, pp. 1080).—Included in this report are a number of articles noted elsewhere in this issue and reprints of Bulletins 54-59 of the department on the following subjects: Analyses of commercial fertilizers (E. S. R., 12, p. 39), the composition and use of fertilizers (E. S. R., 12, p. 38), nursery fumigation (E. S. R., 12, p. 369), the application of acetylene illumination to country homes (see above), a chemical study of the apple and its products (E. S. R., 12, p. 554), and fungus foes of vegetable fruits (E. S. R., 12, p. 359).

A report on the work and expenditures of the agricultural experiment stations for the year ended June 30, 1899, A. C. TRUE (*U. S. Dept. Agr., Office*

of *Experiment Stations Bul. 83*, pp. VI+111).—This includes a critical review of the conduct and general management of the stations, with brief abstracts of all station publications received during the fiscal year ended June 30, 1899; and general statistics relative to organization, publications, principal lines of work, revenue, expenditures, etc.

Crop Reporter (*U. S. Dept. Agr., Division of Statistics Crop Reporter, Vol. II, Nos. 4-6, pp. 8 each; Sup., pp. 4*).—These numbers contain statistical data on the condition of crops in the different States and Territories on August 1, September 1, and October 1, 1900, and a number of articles on miscellaneous subjects, including the following: Foreign wheat and rye crops, the introduction of Hungarian and macaroni wheats, supplementary forage crops, protection of birds, the exportation of corn, recent railroad statistics, foreign crops, the contribution of the Department of Agriculture to the material wealth of the country, the United States cotton exhibit at the Paris Exposition, estimated wheat crop of the world, the grain crops of France, exports of cotton from the United States, the growth of the cotton-mill industry in the South, and exports of wheat from Argentina and India. A supplement to No. 4 contains information on the condition of crops abroad at harvest time and on the outlook as to yield and quality in various countries.

Cotton seed and its products (*Tradesman, 44 (1900), No. 8, p. 61*).—The value of cotton seed and its products during the year ended June 30, 1900, is estimated to have been about \$42,000,000.

Mineral products of the United States, calendar years 1890 to 1899, D. T. DAY (*Chart, Dept. Interior, U. S. Geol. Survey*).—Among other statistics are data showing that the output of phosphate rock in 1899 was 1,515,702 long tons, valued at \$5,084,076, as against \$1,308,885 tons worth \$3,453,460 the previous year. The most valuable output previous to 1899 was 941,368 tons worth \$4,136,070 in 1893.

Changes in railroad freight classifications, E. G. WARD (*U. S. Dept. Agr., Division of Statistics Circ. 12, pp. 43*).—This reports the results of an investigation undertaken to determine the effect of the changes in the classification of freight made January 1, 1900, upon the cost of transporting commodities between New York and Chicago.

Papers read at the spring meeting of the Pennsylvania State Board of Agriculture (*Pennsylvania Dept. Agr. Rpt. 1899., pt. 1, pp. 185-259*).—The following subjects were discussed: The soil—its care and culture, the possibilities of Pennsylvania as a fruit-growing State, bacteriology for the farmer, fruit-culture for profit, potato culture, forage crops, successful dairying, feeding and management of dairy cattle, the dairy interests of Pennsylvania, the leaves of plants and their relation to plant diseases, breeding and care of swine, business methods on the farm, the rural school problem, and our country schools.

Farmers' library list, MIRA L. DOCK (*Pennsylvania Dept. Agr. Bul. 65, pp. 30*).—This gives a list of some 400 books suitable for an agricultural library, with name of publisher and retail price of each.

Agricultural education in English rural schools (*West Indian Bul., 1 (1900), No. 4, pp. 428-444*).—Outline suggestions for teaching agriculture in English rural schools as issued by the board of education in England.

NOTES.

COLORADO STATION.—B. U. Dye, of Rockyford, has been appointed a member of the governing board of the station to succeed A. L. Kellogg; J. L. Chatfield has been reappointed, and Gov. J. B. Orman succeeds Gov. C. H. Thomas as an ex officio member of the board.

MARYLAND COLLEGE AND STATION.—W. G. Johnson, entomologist of the station and professor of entomology in the college, has resigned to accept a position on the editorial staff of the *American Agriculturist*, with headquarters at New York City. H. P. Gould, assistant entomologist, has been placed temporarily in charge of the work of the department, until the vacancy is provided for by the board of trustees. Farmers' institutes in the State have been more largely attended than ever before, and the interest manifested in the meetings has been very great.

NEW HAMPSHIRE COLLEGE.—A course in forestry has been established in this college, to extend over one year. It is in charge of F. W. Rane, who now becomes professor of horticulture and forestry. No entrance examination is required, and a certificate will be given after the satisfactory completion of the course.

VIRGINIA STATION.—C. W. McCulloch, assistant veterinarian of the station, has resigned, and H. Bannister, D. V. M., of Roanoke, Va., a graduate of the Veterinary College of the University of Pennsylvania, has been appointed in his place.

UTAH STATION.—John Stewart and B. K. Jones, assistant chemists, resigned their positions January 1, 1901.

NECROLOGY.—Prof. Max von Pettenkofer, renowned for his investigations in medicine, hygiene, and physiology, died by suicide at Munich February 10, 1901, at the age of 82 years. Professor Pettenkofer was born December 3, 1818, at Lichtenheim, Bavaria. He graduated in medicine at Munich in 1843, and three years later became an associate professor in the medical faculty at Munich, being advanced to full professorship in 1853. In the meantime he had succeeded his uncle as director of the court pharmacy at Munich, which under him became in effect a scientific laboratory. Early in his career Professor Pettenkofer became interested in public hygiene, and the results of his studies aroused much popular interest, leading to the establishment of chairs of hygiene at the higher educational institutions in Bavaria. One of his greatest achievements was the study of cholera, and the hygienic and sanitary measures necessary to control the disease and prevent its spread. This work led him to studies of typhus, and in general those diseases in whose dissemination soil, water, and air are important factors. He founded the *Archiv für Hygiene*, and was for a long time coeditor of the *Zeitschrift für Biologie*, both of which have for years been leading periodicals in their lines. To those interested in problems relating to the nutrition of man and animals, Pettenkofer's most interesting investigations had to do with the respiration apparatus. In 1862, a description of his apparatus, designed for experiments with man, was published, and the result of experiments with it appeared at frequent intervals later. The apparatus differed from earlier forms in many important particulars. It was adapted for use in experiments with farm animals by a number of German investigators, while a form suited to experiments with dogs and small animals was devised by Voit, who was long associated with Pettenkofer in this line of research. The results obtained by Pettenkofer and his

associates were of the greatest importance as contributions on the fundamental laws of nutrition and bearing on the details of practical feeding. His labors as a teacher continued until 1894, shortly after the semicentennial of his doctorate was celebrated. At this time his colleagues and scientists in institutions in other countries united to do him honor. It is difficult to overestimate the influence which a man of Pettenkofer's stamp exercises upon students in a half century of active work.

Martin Ewald Wollny, the distinguished agricultural investigator, died at Munich January 8, 1901. He was born at Berlin, March 20, 1846. His studies at the Agricultural Academy of Proskau and the universities of Halle and Leipsic were interspersed with several years of practical experience on farms, and he received the degree of doctor of philosophy from the latter university in 1870. In 1871 he was made professor of agriculture in the Agricultural Academy of Proskau, where he remained 3½ years, being called thence to the professorship of agriculture in the agricultural department of the Munich Technical High School, where he remained until his death. Professor Wollny was one of the first and most prominent of investigators to clearly recognize the importance of the physical properties of soils—moisture, temperature, aeration—in the production of plants, and for 20 years the journal, *Forschungen auf dem Gebiete der Agrikulturphysik*, founded by him, was largely filled with accounts of the researches which he made in this field. He was a prolific writer and contributed extensively to other journals, several of his résumés appearing in the Record. He was also the author of a large number of books and pamphlets, of which the following are the more important: *Der Einfluss der Pflanzendecke und Beschattung auf die physikalischen Eigenschaften und die Fruchtbarkeit des Bodens* (1877), *Ueber die Anwendung der Elektrizität bei der Pflanzenkultur* (1883), *Ueber die Thätigkeit niederer Organismen im Boden* (1883), *Saat und Pflege der landw. Kulturpflanzen* (1885), *Die Kultur der Getreidearten* (1887), *Welche Moorgattungen eignen sich für die Anlegung von Kimpauschen Dammkulturen?* (1890), and *Zersetzung der organischen Stoffe und die Humusbildungen* (1897).

Prof. F. H. Werenskiold, director of the agricultural-chemical control station at Christiania, and a quite prominent contributor to the literature of agricultural investigations in Norway, died suddenly November 13, 1900, at the age of 49 years.

MISCELLANEOUS.—The agricultural council of the Russian Ministry of Agriculture and Imperial Estates has taken steps in the direction of improving the character of the live stock and the live-stock industry in general of that country. At present this industry is said to be far behind that of other countries, the animals kept being inferior and stock raising receiving comparatively small attention from the farmers. The council has recommended the holding of live-stock shows, with prizes for excellence, the establishment of breeding farms and furnishing of expert assistance in purchasing good breeding animals, the maintenance of local breeding establishments where the service of pure-bred animals can be secured, and loans to municipalities and societies for the purpose of purchasing pure-bred animals and providing for their care. In order to carry out the above measures the Ministry of Agriculture, with the concurrence of the Minister of Finance, has recommended an appropriation of 5,000,000 rubles (about \$2,000,000) to begin this work and a quadrennial appropriation of 1,125,000 rubles.

Science reports that an anonymous gift of £50,000 has been made to the Woman's Agricultural College at Reading, England.

Prof. T. Pfeiffer, director of the agricultural-chemical laboratory of the University of Jena, has been called to Breslau to succeed Prof. A. Stutzer, who has gone to Königsberg. Professor Pfeiffer is succeeded at Jena by Dr. Immenhoff, for several years first assistant at the Moor Experiment Station at Bremen.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The EDITOR and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural
Engineering—W. H. BEAL.

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Thomas slag and the determination of its phosphoric acid content, A. N. Papez.....	713
The determination of potash by means of phosphomolybdic acid, Wavelet.....	713
A short method for determining potash in potash salts, H. Neubauer	714
On cellulose determination, C. Counciler.....	714
The detection of foreign coloring matters in canned tomatoes, G. Halphen.....	715
Miscellaneous analyses, H. J. Wheeler.....	717

BOTANY.

The plant covering of Ocracoke Island, T. H. Kearney	720
Xenia, or the immediate effect of pollen, in maize, H. J. Webber	717
On the poisonous properties of compounds of sodium, potassium, and ammo- nium, H. Coupin.....	717
Effect of chemical media on the growth of fungi, L. Planchon	718
The nodule organism of the Leguminosæ, R. G. Smith.....	719

FERMENTATION—BACTERIOLOGY.

	Page.
Studies in systematic bacteriology, F. D. Chester.....	721
Descriptions of certain species of bacteria isolated from cultivated soil, F. D. Chester.....	721
Tobacco bacteria, C. J. Koning	720
Formation and structure of bacterial spores, Mühlshögel	721

METEOROLOGY.

Atmospheric radiation, F. W. Very	723
On solar changes of temperature and variations in rainfall in the region surrounding the Indian Ocean, N. and W. J. S. Lockyer.....	724
Report of the meteorologist, W. H. Bishop	724
Report of the meteorologist, N. Helme	724

WATER—SOILS.

Third report of work in the study of the fertility of soils, S. Bogdanov.....	725
The amount of humus in soils and the percentage of nitrogen in the humus as affected by applications of air-slaked lime and certain other substances, H. J. Wheeler, C. L. Sargent, and B. L. Hartwell.....	727
The causes and the importance of the decomposition of nitrates in soils, W. Krüger and W. Schneidewind	728
Further observations upon the need of lime in Rhode Island soils, H. J. Wheeler and G. E. Adams	732
The chemical functions of certain soil bacteria, F. D. Chester.....	729

FERTILIZERS.

On the question of the preservation of manure and urine, J. König	733
The method of making manure-preservation experiments, T. Pfeiffer, F. Moszeik, and O. Lemmermann.....	733
Denitrification and the action of barnyard manure, T. Pfeiffer and O. Lemmermann.....	734
The fifth year's observations upon the effectiveness of nitrate of potash, as compared with like amounts of nitrogen and potash in form of muriate of potash and nitrate of soda, H. J. Wheeler and J. A. Tillinghast	735
Observations upon the growth of plants on an acid upland soil, limed and unlimed, H. J. Wheeler and J. A. Tillinghast.....	735
On the application of lime upon a sour soil before and after seeding to grass, H. J. Wheeler and J. A. Tillinghast.....	737
Analyses of commercial fertilizers, H. J. Wheeler, B. L. Hartwell, et al.....	737
Fertilizer inspection, C. D. Woods and J. M. Bartlett.....	737

EXPERIMENT STATION RECORD.

VOL. XII.

No. 8.

The systematic investigation of the soils of Russia was begun over twenty years ago by Prof. V. Dokouchayev, of the University of St. Petersburg, under the auspices of the Imperial Economic Society. This work began with the study of the characteristic soil type known as chernozem, but has been extended, mainly by a system of cooperation between Professor Dokouchayev and his pupils in different parts of Russia, to include all of the principal soil types of European Russia. Prominent among these collaborators is Prof. N. Sibirtzev, of the Agricultural and Forestry Institute of Novo-Alexandria. The work is supported partly by Government institutions and partly by private contributions. The published accounts of these investigations include a hundred or more papers in scientific journals and official reports and documents.

In eastern European Russia an important series of soil investigations has been carried on by Professors Sikorzinski and Rizpolozhenski, of Kazan University, and their pupils, working independently of Dokouchayev and his associates. This work is supported by the local governments and by agricultural societies. The published accounts of it include over twenty papers, reports, etc.

The development of soil studies in Russia also owes much to the skillful and accurate analytical work done by the late P. Kostichev, of St. Petersburg, as well as to that of Prof. G. Thoms on the soils of the region Riga, who also pursued their investigations independently.

It is with the work of Dokouchayev, however, that scientists are most concerned. He has founded a new school of soil investigation, the fundamental idea of which is the conception of the soil as an independent natural body. With the collaboration of Sibirtzev, this idea has been utilized in the elaboration of a so-called genetic or natural classification of soils, which, in the study of soil formations, requires a differentiation between the parent rock species and the cultivated horizon. His classification differs fundamentally from the petrographic and physico-chemical classifications commonly followed by investigators who have dealt with soils which have been profoundly modified under culture, rather than with those in a largely virgin condition, as in Russia and in the western United States.

The article in this and the succeeding number of the Record, which is based upon a summary by Dr. P. Fireman of an article (in Russian) by Sibirtzev, discusses this classification, and the soil types of Russia. As will be seen, it groups the soils of the world in seven main zones or belts, as follows: (1) Lateritic soils, (2) aeolian or loess soils, (3) soils of the dry steppes, (4) chernozem, (5) gray forest soils, (6) sod or podzol soils, and (7) tundra soils. The grouping is more complete for the northern than for the southern hemisphere, but even in the former it is not claimed that the zones are continuous or uniform. This is but natural, as in some cases certain soil-forming factors within the zones may predominate over the combined action of the other conditions and agencies involved, and thus impart special features which are not distinctive of the prevailing zonal type. Alkali soils, humus calcareous soils, and marsh soils are examples of intrazonal types.

In addition to these zonal and intrazonal soils there is a third class, incomplete or azonal soils, which are composed almost exclusively of unaltered parent rock with little or no fine earth and humus, and which stand on the borderland between true soils and rocks. In this group are classed soils formed *in situ* and alluvial soils. Of course, in nature there must, under any conditions, be many transitional or modified types or forms which are difficult of classification. The subdivision of the various genetic types into groups and subgroups requires, therefore, not only a study of the dynamic forces which impart to the soil its fundamental characteristics, but also a comparative study of the changes in the composition and structure of the soil and of the parent rock, that is, petrographic, physical, and chemical examinations. In this respect the system of Dokouchayev and Sibirtzev harmonizes with the commonly accepted classification of the German and other Russian investigators, including Mayer, Schübler, Knop, Senft, Ramann, Feska, Kostichev, and others.

Turning from a consideration of the system followed to the results accomplished, we find that the work of soil investigation in Russia has been prosecuted with such vigor and thoroughness that not only has Professor Sibirtzev been able to give in a recent report a soil map showing in colors the areas occupied by the principal types of soils of European Russia (about 22), but also a very complete characterization of these soils, including their origin and history, topographic features, vegetation, climatic conditions, relation to moisture, physical and chemical properties, and behavior under culture. An abstract of this report will appear in a future number of the Record. As a comprehensive, systematic, and thorough piece of work which has been fruitful of remarkable results, these Russian soil investigations are worthy of the careful study of all interested in the subject. They should be of especial interest to American investigators, since the soil conditions of Russia are to a considerable extent duplicated on this continent, a

fact which has been recognized by Hilgard and others, particularly in the study of the virgin soils of America.

As bearing on the much discussed question of the merits of variety testing and the difficulty in drawing safe deductions from the results, the work reported from the Woburn Experimental Fruit Farm with strawberries can hardly fail to be of interest. The report is given in abstract in the present number (p. 747) and evidences much skill and pains in conducting the test of 85 varieties of strawberries for 5 successive years. This station is a private institution, and the work was not undertaken on account of any popular clamor for immediate information. The conclusion reached by the authors is that the results "have entirely failed in proving accurately the respective merits of different varieties of strawberries." Plants of the same varieties grown under the same conditions but of different ages furnished data from which entirely different conclusions might be drawn, according to the season selected for the comparison. Likewise, different varieties of the same age grown under precisely the same conditions, so far as could be determined, gave similar irregular variations in different years. In the same season great variations were found to occur owing to minute variations in the position of the plants. "One variety may in one season yield only one-fifth that which it gives in the next, or one-fifth of what it gives in some other position; whereas in the case of another variety the results are entirely reversed and the yield in the next season or in the other position is 5 times greater instead of 5 times less." The writers go so far as to condemn variety testing in general, and maintain that such work will not lead to a better knowledge of the respective merits of varieties than might be gained from general repute or from experienced nurserymen. This, of course, would not apply to new varieties or those untried in the section. While many will not agree with the broad conclusions reached, the results furnish a striking illustration of the discrepancies to be met with in variety testing, and the warning which the article sounds against extensive work of this character is in accord with the views held by many experiment station workers in this country.

RUSSIAN SOIL INVESTIGATIONS.¹

The systematic study of Russian soils may be said to have begun 22 years ago, when Prof. V. V. Dokouchayev, commissioned by the ancient and renowned "Imperial Free Economic Society," took up the study of the Russian chernozem. Energetic and deeply devoted to his work, he soon gathered around himself a number of gifted and enthusiastic young scientists, who at once attacked various questions relating to soils. Professor Dokouchayev succeeded in organizing in various parts of Russia special soil investigations at the expense of Government institutions and private persons. To Professor Dokouchayev belongs the honor of founding a new school in soil investigations, a school which views the soil as an independent natural body. Among the pupils of Professor Dokouchayev the most celebrated is N. Sibirtzev, the author of the classification of soils, described in this article.²

The second place in importance among the Russian soil investigators unquestionably belongs to P. Kostichev, an independent worker. An eminent chemist and agriculturist, he contributed much to the knowledge of soils by his skillful and accurate analyses of soils.

The following statement regarding the classification of soils and the characteristics of Russian soils are taken from the reports of Sibirtzev referred to above.

GENETIC CLASSIFICATION OF SOILS.

The conception of a soil as a natural body having a definite genesis and a distinct nature of its own has led to attempts to create a natural classification of soils on a scientific basis. To this important branch of the study of soils the Russian investigators have made important original contributions, and established new principles for the systematic study of soil formations, not confounding the latter with either rock species or with the cultivated horizon of the ground. The

¹Translated and condensed from the original articles of N. Sibirtzev, by Dr. Peter Fireman.

²Genetic classification of soils, N. Sibirtzev (*Zapiski Novo-Alexand. Inst. Selsk. Khoz. Lysov.* Memoirs of the Instit. of Agric. and Forest. at Novo-Alexandria, Government of Lublin, IX (1895), pt. 2, pp. 1-23). Brief survey of the chief soil types of Russia (*Ibid.*, XI (1898), pt. 3, pp. 1-40). The latter memoir was presented in French (*Étude des sols de la Russie*) to the Seventh International Geological Congress at St. Petersburg, in August, 1897.

scientists of Western Europe have been at a disadvantage regarding this question, since they have for the most part had to deal with soils only slightly developed, shallow or easily washed away, mixed with various geological deposits, and at the same time strongly altered by cultivation. In reality the "tilled layer of the soil" of Western Europe, under the influence of the intensive and deep cultivation there practiced, is an artificial mixture of natural soil and of the underlying primitive rock. This accounts for the geo-petrographic and the physico-chemical classification of soils in vogue among the scientists of Western Europe.

America, with its virgin soils, vast, frequently still untilled plains, prairies, forests, deserts, and barren alkali lands, and clearly defined climatic, physico-geographical and geo-botanical zones offers an excellent field for the study of natural soils. As a matter of fact the American investigators of the soil, especially Hilgard, have already come to a clear recognition of the soil as an independent formation and have established natural soil types.

The study of soils which has been so industriously carried on in Russia the last 20 to 30 years under the leadership of Dokouchayev and Kostichev has for its starting point the idea of the soil as a natural body which occupies an independent place in the series of formations of the earth's crust.

According to the definition of Professor Dokouchayev, under the term "soil" must be understood the surface horizons of the rocks, more or less altered under the simultaneous influence of water, air, and various organisms, living as well as dead. In other words, the soil is the superficial horizon of rocks in which the general processes and phenomena of weathering, transportation of particles, etc., combine with the biological processes and phenomena due to the influence of plants, animals, and micro-organisms. Weathering of rocks which takes place independently of the action of organisms yields products which must be considered as rocks, and the study of such products belongs to petrography. These products may replace and may be converted by cultivation and fertilizing into artificial soils, but must be distinguished from natural soils. However, such soils are of rare occurrence. It is well known that many organisms, such as nitrifying bacteria, lichens, alpine plants, etc., play an important part even in the first stages of the disintegration of the massive and sedimentary rocks. On the other hand, in the class of natural soils should not be included the mechanical deposits of dead organisms or their excretions (peat beds, guano, and the like) and those derived from rocks of organic origin.

As a superficial geo-biological formation of the earth's crust, the soil differs from the parent rock from which it is derived in composition, complexity of the dynamic factors, and external morphological peculiarities. Natural soils vary with (1) the petrographic type of the

parent rock; (2) the nature and intensity of the processes of disintegration, in connection with the local climatic and topographic conditions; (3) the quantity and quality of that complexity of organisms which participate in the formation of the soil and incorporate their remains in it; (4) the nature of the changes to which these remains are subjected in the soil, under the local climatic conditions and physico-chemical properties of the soil medium; (5) the mechanical displacement of the particles of the soil, provided this displacement does not destroy the fundamental properties of the soil, its geo-biological character, and does not remove the soil from the parent rock;¹ and (6) the duration of the processes of soil formation.

All these may be termed genetic conditions of formation of natural soils. Such existing types of natural soils always correspond to a definite combination of the soil-forming factors. The parent rocks, the organisms (with their subsequent transformations), and the physico-geographical conditions of the country, including climate (humidity, temperature), recent geo-physical history and relief, are the chief agents of soil formation. The correlation among these factors may assume various forms, a certain connection or parallelism being observed either among all or only a part of them. Thus, the composition and distribution of the ancient sedimentary and crystalline rocks do not, of course, depend on those conditions (even climatic) of the country to which the formation of the existing soils is subject. But the weathering of the rocks and, in general, all the physical and chemical processes which take place in the soil are influenced by climatic conditions. Climates in which wet and dry seasons alternate produce laterites, the climatic conditions governing the biological processes which result in the formation of lateritic soils. Eolian loess and pulverulent rocks which resemble it are characteristic of continental regions with a dry climate. From this point of view the nature of a given soil type presents, in a certain measure, a function of the climate.

The soils of a given territory are also influenced by the life activities and the dead remains of plant and other organisms. The soils influence the development and the life activity of these organisms and their decomposition after death. On the other hand, the character of the plant growth, for example, plays not only a direct, but an intermediate rôle in the formation of the soil. The relief of the soil has an important influence in determining the drainage, temperature, etc. And lastly, the relative duration of the soil-forming processes which have gone on since the removal of the glacial or water cover, as for example, the successive changes which have taken place in the climate, the encroachments of the forests upon the prairies, the spread of marshes, the drying up of the soil, etc., must in their turn influence the character

¹Otherwise the soil is converted into alluvium, diluvium, etc., or, in general, into mechanical deposits of secondary formation.

of the soils. The knowledge of the laws and the forms of these influences make it possible to obtain from the study of soils a basis for the reconstitution of the recent past of the country and for sketching its recent geo-physical history. The essential factors determining the characteristics of natural soils are as follows:

(1) The conditions and the factors of the origin of the given soil type (the material and the organic agents); (2) the morphological properties of the soil, *i. e.*, its color, depth, constitution,¹ structure, transition into the parent rock, etc.; (3) the physical, chemical, and chemico-biological properties; (4) the modification with the type; and (5) the geographical and topographical distribution.

The natural classification of soils can be elaborated, taking the genetic principle as a starting point. In establishing the chief groups of soils the existing types of formation of soils in nature must be recognized, the homogeneous or similar combinations of soil-forming agents (such as climate, parent rocks, organisms, relief of country, etc.) must be formulated. As is well known, the weathering of the rocks alone, provided it takes place under similar physico-geographical conditions, may efface to a considerable degree the differences which exist among the rocks, and may give alluvial products of fine earth more closely resembling one another than the original rocks; this similarity is more manifest when the biological factors also tend to produce a uniform result. We can, consequently, establish an ensemble of natural conditions which will produce as a result soils, say, of the chernozem group. A characteristic feature of these soils is the peculiar accumulation of humus under the sod. Wherever analogous conditions prevail soils of the chernozem type are formed. Similarly, we know the climatic conditions which favor atmospheric-eolian weathering, the pulverization of the soft rocks, and where these conditions obtain eolian dust soils result. The soils of these groups in their principal features are the natural resultant of the physico-geographical type of the given continental region or zone. The soil of the different zones will, of course, not be uniform, but will exhibit similarity to the extent to which their content of fine earth and humus reflect the analogous influences of a definite and constant combination of geo-physical factors of soil formation.

In this way the first class of zonal soils is determined. In the proc-

¹ A vertical section of a soil always shows two, three, or even more horizons, detailed descriptions of which are given in Russian works on soils. Of these horizons the most remarkable are: (1) The upper horizon, the most uniformly and strongly colored by humus; (2) the lower horizon, distinguished from the upper by its structure and color and gradually merging into the subsoil; and (3) the subsoil or parent rock preserving its fundamental petrographic features. The first two horizons taken together give the depth of the surface soil. Sometimes in these horizons sub-horizons can be distinguished, with peculiar differences in composition, structure, and tint (alkali soils, forest soils, etc.).

esses of their formation general ectodynamic and special biological phenomena manifest themselves in accordance with the physico-geographical types of continental zones. Such are the following types of soils:¹

(1) Lateritic soils. These are the soils of the tropical and subtropical regions with alternating wet and dry seasons.

(2) Atmospheric-eolian soils. Formed of the dust rocks in the central regions of the different continents under arid conditions.

(3) Soils of dry steppes or steppes deserts. Being formed of argillaceous and arenaceous primitive rocks, they are chestnut and fawn-colored.

(4) Chernozem soils. These occur in connection with the grass steppes or prairies of the temperate or warm-temperate regions. They develop best from argillaceous rocks.

(5) Soils of wooded steppes and deciduous forests (gray soils), resembling chernozem soils, but differing from them in the conditions of their origin, and in their morphological and other properties.

(6) Sod soils and podzol soils² which are peculiar to the temperate-frigid zone. They are typically developed under mixed woods and bushes and are ordinarily accompanied by concretions.

(7) Tundra soils. These are formed from the clays and argillaceous sands of the tundras, in a cold climate with a very long winter. They are characterized, to a greater or less degree, by being perpetually frozen (the subsoil waters are in a solid state).

The groups of soils named represent the soil zones or belts into which the surface of the continents may be divided.

The lateritic soils belong to the coastal zone of tropical and subtropical continental regions which is broken and cut up by seas. After them follow toward the north and south, in the order indicated in the above enumeration, the regions with the other soil types. In the zone of the continental plateaus and the inclosed or partly inclosed plains of the northern hemisphere—in central and southwestern Asia (China Persia, Arabia, Turkestan), in the Caspian region, in northern Africa, and in the western and southwestern States of North America are found the atmospheric-eolian soils and the soils of the steppes deserts. In the southern hemisphere are corresponding zone soils covering central Australia, inland sections of southern Africa (the country of the Hottentots, the region to the south of the sources of the Zambezi

¹Only the best known types are mentioned here, use being made of the results of studies of the natural soils of Russia, Western Europe, of some regions of Central and Southern Asia, of America, etc., partly of Australia, and Africa.

²Podzol soils are unproductive soils consisting mainly of very fine sand, but containing more organic matter than their color would indicate. They resemble ashes in appearance, hence the name "podzol," which indicates this resemblance. They correspond nearly with the Bleisand of Germany.

River), and Argentina. In the open grass plains, such as the Hungarian, Russian, and Siberian steppes or American prairies in the northern hemisphere, and the eastern provinces of Argentina (Entrerios, Corrientes, Buenos-Ayres) in the southern hemisphere, occur the soils of the chernozem group. In Asia, Europe, and North America between the chernozem and tundra soils those of the fifth and sixth group are situated. In the southern hemisphere there is no such complete grouping of soils as in the northern. This is due to a different configuration of the southern continents.

The system of soil zones enumerated above is only an ideal general scheme. In reality no one of these zonal types of soils embraces the continental surface of the globe in a continuous belt. All of them extend in interrupted bands and spots, now expanding enormously in breadth, now becoming narrow, now intermixing with one another at their boundaries, now forming circumscribed areas separated by greater or smaller distances from the principal zones. The reason for this is found in the effect of local orographic, geological, and climatic peculiarities, which interfere with the development or cause a displacement of certain soils.¹

The division into types distributed in zones or belts does not begin to exhaust the whole variety of natural soils. As stated above, among the soil-forming factors there are some which may individualize themselves by diverging from the concordant action of the other factors. Thus, for example, a particular composition of the parent rock may retain its influence on the soil and thus impart special features which are not proper to the dominant zonal type; a similar effect may be caused by the local saturation of soils with water, due to the configuration of the surface. Humus soils of this second class may be called intrazonal or semizonal. They are dispersed among the main zones in circumscribed areas and spots, occurring chiefly, although not exclusively, in connection with some of the zones. Certain types of the intrazonal soils are met with in those zones whose general conditions favor the most or interfere the least with the action of the individualizing factor.

There are undoubtedly very many types of intrazonal soils. We shall mention the following as examples: (1) Alkali soils, which form when the parent rock contains soluble salts and the drainage is poor. Since the salt contents of the rock may depend on causes purely geological, having no direct connection with the other soil-forming factors, there is, generally speaking, no zonal regularity to be observed in the distribution of alkali soils. However, they occur mostly in the arid regions

¹In Russia, *e. g.*, the soils of the steppes deserts extend to the south and south-east of the chernozem, and in North America to the west and southwest (in conformity with the increasing aridity of the climate). It may be added that vertical zones may also be observed on broad slopes and plateaus which appear in a measure as local repetitions of the horizontal zones in an analogous order.

of Europe, Asia, America, Africa, and Australia, *i. e.*, in the second, third, and part of the fourth zones. (2) Humus-calcareous soils. Humus-containing soils are formed from calcareous rocks (limestone, marble, chalk, etc.) accumulating much humus in consequence of the rapid leaching out of the calcium and magnesian carbonates and the retarded decomposition of the organic remains in the feebly alkaline medium. (3) Marshy soils. Under this term are understood soils which owe their origin to the influence of stagnant waters (water-logged soils) dispersed over the surface of continents, wherever the relief and the hydro-geological conditions favor their formation. They occur most frequently in temperate and frigid zones, although sometimes found in the arid zone. They are formed (a) in a medium of fresh water (sour meadows, the marshes of the lowlands), or (b) in sections which are or have been subject to inundations by the sea or by the waters of estuaries (sea marshes, salt marshes, delta marshes, etc.). The different stages in the formation of the swamps, the diverse composition of the organisms, the character of the aqueous medium, the drying up of the marshy basin due to various causes, give to the soils of this type a great variety.

Lastly, there are many natural soils which are composed of the unaltered parent rock (when forming *in situ*) to the almost complete exclusion of fine earth and humus, or which are formed by a mixed process (1) by the mechanical deposition of particles, mineral as well as organic (alluvium); and (2) by the periodic action on the alluvial deposits of the special factors which form humus soils. The soils of this nature stand, so to speak, on the border line between soils proper and rocks, in one case merging into soils, in another approaching rocks. They form the third class of incomplete or azonal soils; they are met with everywhere. When they are formed *in situ*, outside of alluvial depressions and valleys, they can be divided into two large groups, (1) crude soils and (2) skeleton soils. By crude soils are meant those in which there is a considerable quantity of clay-like particles (clays, silt, and fine sand), but in which the horizon of vegetable humus is not clearly defined. Every humus soil passes downward into a crude soil, but the term is applied here only to those soils which are wholly or almost wholly crude. The name skeleton soil is applied to those in which granular and sandy, gravelly, or pebbly elements, or in general, the skeleton mechanical elements which take the place of the humus and fine earth, entirely predominate.

Among the conditions which conduce to the formation of crude and skeleton soils are the following:

(1) Unalterability or difficult alterability of the parent rock or of the rocky components of the soil (sand, rock fragments, pebbles, compact sedimentary rocks, etc.).

(2) The washing off of the humus horizon by the snow and rain waters (crude soils on hills and slopes).

(3) The short duration of the processes of soil formation (undeveloped soils on comparatively recently uncovered or deposited rocks).

(4) The interference with the soil-forming processes by unfavorable climatic influences (especially in deserts and arctic regions).

The fundamental feature of alluvial soils is their formation with the aid of mechanical transportation and deposition of particles by water. Such are the soils of the river valleys. Alluviums, however, must not be confused with alluvial soils. The former are purely mechanical deposits of varying depth—geological formations—while an alluvial soil is the horizon of this deposit which has been subjected to the action of the general dynamic agents of weathering and to the influence of organisms.

To sum up the above considerations, natural soils may be divided into the following genetic classes and types:

Class I.—Zonal soils, complete.

Type 1. Lateritic.

2. Atmospheric eolian.

3. Soils of the steppe, deserts or dry steppes.

4. Chernozem.

5. Soils of wooded steppes and gray forest soils.

6. Sod soils and podzol soils.

7. Soils of the tundras.

Class II.—Intrazonal soils.

Type 1. Alkali lands.

2. Humus-calcareous soils.

3. Marshy soils, etc.

Class III.—Incomplete or azonal soils.

Soils formed *in situ*.

(a) Crude } of various groups.
(b) Skeleton }

Alluvial soils (of different types).

In nature transitional forms are found among the soils of the various genetic types. These transition types may result (1) from the fact that the soil-forming agents (*e. g.*, the climatic conditions) do not change suddenly, but more or less gradually, and thus can produce intermediate results; or (2) from the changes which take place in the soils themselves in the course of their formation and development. Soils may pass through various phases and forms of development in correspondence with the external influences which act upon them. Thus, some alkali soils, losing little by little their salts by leaching, are converted into soils of dry steppes or even into chernozem. Alluvial soils, having passed out of the sphere of river inundations, approach the local zonal types. If a locality, for one reason or another, loses its

drainage, the soils may become swampy, and, *vice versa*, marshy soils, by drying and drainage, lose their characteristic peculiarities and approach other local types. If, during the period of formation of chernozem, the steppe or prairie is encroached upon by forests, the latter change the structure and composition of the soil in the direction of soils of wooded steppes and forest soils, etc.

The genetic types of soils are large categories which include many subtypes, groups, and subgroups. A detailed classification of soils may be based on two kinds of facts: (1) On the degree or force and on the variation of those dynamic processes which impart to the soil the fundamental features of the given genetic type. Thus, for example, there exist conditions which lead to the formation of chernozem soils, but these conditions may vary, may deviate from a certain mean, and, in consequence of these fluctuations, from one and the same or a similar parent rock there may result unlike chernozems with a different content and quality of humus. (2) On the changes in the composition and structure of the soils in connection with the composition and structure of the parent rocks. The subdivisions of this category are based upon (*a*) the physical properties of the soils, *i. e.*, their skeleton and fine earth; (*b*) the chemical and chemico-petrographic peculiarities of the soils. Chernozem, for instance, may be argillaceous, subargillaceous, subarenaceous, marly, phosphoric, etc. The division of the genetic types and subtypes of soils into groups and subgroups, a division based on the mechanical, physical, and chemical properties of the soil mass, connects the system here described with the common soil classifications of the German and Russian authors (Mayer, Schübler, Knop, Senft, Ramann, Feska, Kostichev, and others). It is believed that a soil classification such as that described above, which is based on the quantitative contents in the soil of skeleton and fine earth and on the particular character of these two constituents (mechanico-physical groups and subgroups), is more general than the commonly accepted system. Following these subdivisions, or, more properly, within them, are the chemical subdivisions based on (1) the chemico-petrographic composition of the soil skeleton, (2) the composition of the siliceous substances of the fine earth of the soil (the chemical nature of the soil clay, of the zeolitic compounds, etc.), and (3) the oxids and salts containing no SiO_2 , their quantity and nature (carbonates of alkaline earths, of alkalis, ferrous and ferric oxid, phosphates, sulphates, their solubility in water, etc.).

(Concluded in next number.)

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Thomas slag and the determination of its phosphoric acid content, A. N. PAPEZ (*Ztschr. Landw. Versuchsw. Oesterr.*, 3 (1900), pp. 695-713; *abs. in Chem. Centbl.*, 1900, II, No. 24, p. 1213).—The author made comparative tests of methods of determining solubility in citrate solution, citric acid, and formic acid, as well as of determining total phosphoric acid. The results with citrate solution are considered unreliable. Those with citric acid and formic acid solutions were more satisfactory. For preparing the solution for the determination of total phosphoric acid the author recommends boiling 0.5 gm. of the slag with 100 cc. of nitric acid of specific gravity 1.25 for 15 to 20 minutes. The phosphoric acid may be precipitated by means of the ordinary, the Wagner, or the concentrated molybdic solutions. The use of different kinds of magnesia mixture did not affect the results.

The determination of potash by means of phosphomolybdic acid, WAVELET (*Ann. Chim. Analyt. et Appl.*, 5 (1900), pp. 289-292; *abs. in Chem. Centbl.*, 1900, II, No. 12, p. 689).—The directions given are as follows: Dissolve 10 gm. of the substance in 200 cc. of water and to 20 cc. of this solution add an excess of the molybdic solution (prepared as described below), evaporate to dryness on the water bath, grind the residue to a powder, add 40 cc. of nitric acid (1 to 10), heat on the water bath, and filter after cooling. Wash the precipitate thoroughly with dilute nitric acid, dissolve in ammonia, and determine phosphoric acid in the solution by means of magnesia mixture in the usual way. Potash is calculated by multiplying the weight of the magnesium pyrophosphate by 0.64.

The potash may also be determined by titrating the ammonium-magnesium phosphate with lead nitrate. For this purpose dissolve the precipitate on the filter in 20 cc. of nitric acid (1 to 20), add phenolphthalein and neutralize with ammonia, add 1 cc. of acetic acid, make the volume to 100 cc., and to 50 cc. of this solution add 5 cc. of 5 per cent sodium acetate solution, and 3.5 per cent lead nitrate solution until a drop of the solution gives a yellow coloration with potassium iodid solution. A blank test is made for correcting the results.

The percentage of potash is calculated by multiplying the corrected number of cubic centimeters of lead nitrate by 1.99.

The phospho-molybdic solution used is prepared by dissolving 140 gm. of sodium carbonate (Na_2CO_3) and 20 gm. of sodium phosphate (Na_2HPO_4) in 500 to 600 cc. of water, adding 70 gm. of freshly ignited molybdic acid (MoO_3), 200 cc. of nitric acid, making the volume to 1 liter, allowing to stand 24 hours, and filtering. This reagent gives with potassium, ammonium, and thallium salts as well as alkaloids, a yellow precipitate soluble in ammonia and insoluble in nitric acid. The molybdenum content of this precipitate varies, but the ratio of potash to phosphoric acid remains constant at 1.99.

A short method for determining potash in potash salts, H. NEUBAUER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 8, pp. 481-502).—A method for the estimation of potash in crude salts containing mixtures of sulphates and chlorids of potassium, sodium, magnesium and calcium. To a 25 cc. solution of 0.5 gm. of substance a few drops of hydrochloric acid are added and enough platinic chlorid for precipitating the potash as double chlorid salts. The solution is evaporated to dryness in a water bath, moistened with about 1 cc. of water, and rubbed with a glass rod with a flattened end. About 30 cc. of alcohol are added in successive portions of 10 cc. and the mass rubbed after each addition. The material is covered and allowed to stand half an hour, receiving an occasional rubbing during that time. It is then transferred to a Gooch crucible and washed with ether. The crucible is then gently heated while a current of hydrogen gas is introduced through the lid. After 5 minutes the flame is increased to a dull red heat and continued for 20 minutes. The residue in the crucible is first moistened with cold water, then washed about 15 times with hot water, and finally with a 5 per cent nitric acid solution, without the use of a filter pump, for about 30 minutes. The washing should be thorough in order to remove the salts. After this the residue is washed with hot water, ignited, and weighed. The factor 0.48108 is used for estimating the K_2O .

On cellulose determination, C. COUNCLER (*Chem. Ztg.*, 24 (1900), No. 35, pp. 368, 369).—This is a comparison of the Schulze-Henneberg, Müller, and Lange methods, and a modification of the Müller method proposed by the author. In the Müller method the dried substance is extracted with a mixture of strong alcohol and benzol, and then with hot water. The residue is treated with bromin water and then with dilute ammonia, heating nearly to boiling. This treatment with bromin water and ammonia is repeated a number of times until the material is not colored when heated with dilute ammonia. It is then washed with water and with boiling alcohol and dried at 110 to 115° C. While Müller claims that 3 or 4 treatments with bromin and ammonia are sufficient, the author finds that sometimes as many as 20 are

required. He has attempted to shorten the method by previously heating the sample with calcium bisulphite solution (8° Baumé) for 4 to 8 hours at 110 to 140° C. in a sealed tube, and then proceeding as before.

Widely different results were obtained by the 4 different methods, the modified Müller and Lange methods giving the lowest results. The Schulze-Henneberg and Müller methods are both believed to be too complicated and tedious, and the author believes that an exact and simple method for determining cellulose has yet to be devised.

The detection of foreign coloring matters in canned tomatoes, G. HALPHEN (*Jour. Pharm. et Chim.*, 6. ser., 11 (1900), pp. 169-172; *abs. in Analyst*, 25 (1900), Aug., p. 206).—Directions are given for detecting coal-tar colors and cochineal. The desiccated pulp is treated with glacial acetic acid for 10 minutes and the liquid then mixed with twice its volume of 90 per cent alcohol and filtered after 10 minutes' standing. The filtrate is diluted with 10 times its volume of water and tested with a small amount of silk floss, the liquid being boiled for at least 15 minutes. In the presence of coal-tar colors the silk assumes a rose or salmon color.

In testing for cochineal the dried residue is thoroughly mixed with hydrochloric acid and the paste shaken with twice its volume of 90 per cent alcohol. The filtrate is diluted as before and shaken with amyl alcohol. The 2 layers formed are separated with the aid of carbon bisulphid. If cochineal is present the filtrate will have a rose color, and the coloring matter may be extracted with amyl alcohol, forming a yellowish red solution. The latter may be tested with uranium acetate, with which it gives a characteristic green coloration.

Handbook of industrial organic chemistry, S. P. SADTLER (*Philadelphia: J. B. Lippincott Co.*, 1900, 3. ed., pp. XVIII+543, figs. 126).—In this edition every chapter has been revised and new matter added, those on natural and artificial dye colors being largely rewritten. Some old and less important matter has been omitted and the bibliographical data and statistics have been brought up to date.

Commercial organic analysis, A. H. ALLEN (*Philadelphia: P. Blakiston's Son & Co.*, 1900, vol. 3, pt. 1, pp. XVI+589).—This is a revision and enlargement by J. Merriett Matthews, and treats of tannins, dyes and coloring matters, and writing inks.

The oil chemist's handbook, E. HOPKINS (*New York: John Wiley & Sons*, 1900, pp. VIII+72).

Synoptic tables for the analysis of fertilizers and soil amendments, P. GOUPIE (*Tableaux synoptiques pour l'analyse des engrais et des amendements. Paris: J. B. Baillière & fils*, 1900, pp. 80, figs. 3).—These tables give concise directions for the preparation of reagents carrying out the determinations and calculating the results in the analysis of the ordinary fertilizing materials and amendments, including fertilizing chemicals, guano, dried blood, horn, meat, solid and liquid manure, poudrette, vinasse, sewage, lime, limestone, marl, and gypsum.

The preparation of an exact standard acid, G. L. HIGGINS (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 11, pp. 958-962, figs. 2).—The method and apparatus used in the preparation of a standard acid from gaseous hydrochloric acid are described.

The determination of potash by means of phospho-molybdic acid (*Ann.*

Chim. Analyt. et Appl., 5 (1900), pp. 345-347).—A letter to the editor by von Garola calling attention, in connection with Wavelet's article noted above (p. 713), to Raulin's work on the same subject.¹

The electrolysis of copper sulphate as a basis for acidimetry, C. A. KOHN (*Jour. Soc. Chem. Ind.*, 19 (1900), No. 11, p. 962).—Tests of this method of preparing a standard acid are reported.

Estimation of nitrites in the presence of nitrates, H. PELLET (*Ann. Chim. Analyt. et Appl.*, 5 (1900), p. 361; *abs. in Chem. Ztg.*, 24 (1900), No. 92, *Repert.*, p. 339).—This method depends upon the fact that nitrites in the presence of ferrous salts and acetic acid are broken up, while nitrates are not affected. The total nitrogen of the nitrites and nitrates is determined by treatment with ammonium-ferrous sulphate and hydrochloric acid, and measuring the nitric oxid. The nitrites are then determined in a second sample by treatment with ammonium-ferrous sulphate and acetic acid. Or both nitrites and nitrates may be determined in the same sample by first treating with the iron salt and acetic acid, and after reading off the volume of gas, adding hydrochloric acid to decompose the nitrates.

Estimation of nitrites with nitrates, L. DE KONINCK (*Ann. Chim. Analyt. et Appl.*, 5 (1900), p. 365; *abs. in Chem. Ztg.*, 24 (1900), No. 92, *Repert.*, p. 339).—In order to determine the nitrates with nitrites, by the method of Pellet, as noted above, the author finds that 30 to 40 cc. of fuming hydrochloric acid should be added. With this precaution the method was found accurate.

Contribution to the determination of the oxidizable substances in water, E. RUPPIN (*Ztschr. Untersuch. Nahr. u. Genussm.*, 3 (1900), pp. 676-681; *abs. in Chem. Centbl.*, 1900, II, No. 20, p. 1088).

The determination of air in water, H. PELLET (*Ann. Chim. Analyt. et Appl.*, 5 (1900), pp. 369, 370; *abs. in Chem. Centbl.*, 1900, II, No. 20, p. 1089, fig. 1).

The analysis of sour milk, F. J. LLOYD (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), pt. 2, pp. 98-105).—By means of a number of series of experiments the author shows the decrease in the total solids of milk after souring. The result corrected by adding one-third of the percentage of lactic acid to the total solids was approximately accurate. This was true for milk 48 hours or 5 weeks old. When the samples contained other than lactic acid micro-organisms, the rule did not apply. The author recommends sterilizing reserve samples of milk to overcome the difficulty and prevent any injustice on a revision of the analysis.

Nicotin in tobacco, G. D'UTRA (*Bol. Agr. São Paulo*, 1. ser., 1900, No. 3, pp. 138-152).—Determinations of nicotin in samples of a large number of different kinds of tobacco are reported and discussed, and the agricultural applications of nicotin (tobacco extracts) are explained.

On the presence of invertin and sucrose in grapes, V. MARTINAND (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 20, pp. 808-810).

The estimation of free sulphuric acid in wines, F. CARPENTIERI (*Staz. Sper. Agr. Ital.*, 33 (1900), pp. 307-340).

The estimation of the dry matter in wine by a specific gravity method, F. CARPENTIERI (*Staz. Sper. Agr. Ital.*, 33 (1900), pp. 341-356).

The adulteration of olive oils, W. K. FERREIN (*Farmazft*, 7 (1900), p. 1007; *abs. in Chem. Ztg.*, 24 (1900), No. 92, *Repert.*, p. 339).—The substances used in adulterating olive oil are given and the methods of determining the amounts of the adulterants.

On the simultaneous occurrence of saccharose and gentianose in the fresh roots of gentian, E. BOURQUELOT and H. HÉRISSEY (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 19, pp. 750-752).

Production of nitric acid from air by means of the electric flame, A.

¹ *Compt. Rend. Acad. Sci. Paris*, 110 (1890), p. 289.

MCDUGALL and F. HOWLES (*Mem. Manchester Lit. and Phil. Soc.*, 44 (1900), pt. 4, No. 13, pp. 1-19; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 456, II, p. 651).—Reports tests of the influence of different forms of combustion chamber, strength of current, mixtures of oxygen and nitrogen, and temperature upon the rate of formation of nitric acid.

On the simultaneous production of two nitrogen salts in the crater of Vesuvius, R. V. MATTEUCCI (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 23, pp. 963-965).

Miscellaneous analyses, H. J. WHEELER (*Rhode Island Sta. Rpt.* 1899, pp. 146-151).—Analyses are reported of salt, sodium carbonate, double carbonate of potash and magnesia, muriate of potash, sulphate of potash, carbonate of potash, acid phosphate, floats, Thomas slag, aluminum phosphate, waste liquor from rendering works, nitrate of potash, nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, and soot.

On an improved Geissler potash apparatus, J. WETZEL (*Ber. Deut. Chem. Gesell.*, 33 (1900), No. 18, pp. 3393, 3394, fig. 1).—The improvement consists of the introduction of small movable glass funnels into the absorption bulbs, which collect and hold the gas bubbles for some time beneath the surface of the potash solution, thus insuring more complete absorption.

BOTANY.

Xenia, or the immediate effect of pollen, in maize, H. J. WEBBER (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul.* 22, pp. 44, pls. 4).—The author reviews much of the more recent literature on the supposed immediate or direct effect of pollen on the character of seeds and fruits, and gives in detail the records of a number of experiments and results in crossing different varieties and races of corn. The results obtained are discussed at considerable length, and it is shown that in the experiments, particularly in the case of dent races with a starchy endosperm crossed with sweet corn with a sugary endosperm, there was no indication of modification of the chemical constitution. It seems probable that in a great majority of cases the results confirm Correns's proposition, viz, that the influence of foreign pollen exhibits itself only in the endosperm, all parts which are outside of this remaining entirely uninfluenced, and that the influence extends only to the color of the endosperm and the chemical composition of the reserve materials—the starch or dextrin therein. In all cases the size and form of the kernels remain unchanged. The experiments and observations of the author favor the theory that xenia in maize is caused by fecundation of the embryo sac nucleus by one of the male nuclei, as suggested by De Vries and Correns; and the evidence now available seems to indicate that those cases of supposed xenia where the pericarp is influenced must be due to other causes or explained as errors of observation.

On the poisonous properties of compounds of sodium, potassium, and ammonium, H. COUPIN (*Rev. Gén. Bot.*, 12 (1900), No. 137, pp. 177-193).—A report is given on the toxic equivalent of the principal compounds of sodium, potassium, and ammonium in regard

to young plantlets of wheat when grown in distilled water. The toxic equivalent is the minimum weight of the substance dissolved in 100 parts of distilled water which will kill the plant. The figures given in the accompanying table are the average of a large number of experiments, and show the relative poisonous properties of the substances named. The more common of the substances experimented with are given in the following table:

Amount of different substances required to kill wheat plantlets in water cultures.

Substance.	Per cent.	Substance.	Per cent.
Sodium chlorid	1.8	Sodium chromate	0.125
Potassium chlorid	1.9	Potassium chromate0625
Ammonium chlorid	1.6	Ammonium chromate0625
Sodium bromid	1.2	Sodium bichromate0064
Potassium bromid1	Potassium bichromate03125
Ammonium bromid	1	Ammonium bichromate025
Sodium iodid05	Sodium sulphate8
Potassium iodid05	Potassium sulphate	2.3
Ammonium iodid33	Ammonium sulphate	2.5
Sodium fluorid14	Sodium phosphate	1.5
Potassium fluorid09	Potassium phosphate	6
Ammonium fluorid04	Ammonium phosphate4
Sodium nitrate	1.7	Sodium carbonate	1.1
Potassium nitrate	3	Potassium carbonate	1.7
Ammonium nitrate	3.9	Ammonium carbonate3
Sodium oxalate (neutral)125	Sodium chlorate058
Potassium oxalate (neutral)25	Potassium chlorate2
Ammonium oxalate (neutral)125		

Effect of chemical media on the growth of fungi, L. PLANCHON (*Ann. Sci. Nat. Bot.*, 8. ser., 11 (1900), pp. 1-248, pls. 4, figs. 63; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 4, p. 496).—The results of a large number of experiments on the growth of 20 species of Dematiæ in a number of different nutrient fluids and chemical solutions are given. The terms fumagoid, alternarioid, macrosporoid, etc., are noted to denote the different growth forms in the various species. The best culture medium was found to be potato acidified by lying for a quarter of an hour in 1 per cent sulphuric acid. It is found that plants of this class are more subject to morphological diversity, depending on the chemical composition of the medium, than are the Mucedinæ. These modifications affect the vegetative change more than the reproductive organs and are believed to be a mode of defense against desiccation and the injurious effects of the medium. The most common forms of such modifications are the thickening and encysting of the cell wall, a change in the form of the filament itself, the production of chlamydospores of isolated cells capable of germinating, or of toruloid forms in which the mycelial filament has entirely disappeared. All kinds of transitional forms between the extremes were noted. The author, as a result of his investigations, regards *Dematium pullulans* and *Cladosporium herbarum* as distinct species. Two new species of *Altemaria* are described, *A. varians* and *A. polymorpha*.

The nodule organism of the Leguminosæ, R. G. SMITH (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 11, pp. 371, 372).—A brief note is given of the investigations of the author on the organisms producing tubercles on the roots of Leguminosæ. The organisms were grown in a number of media, and the author states that the appearance of these organisms depends very largely upon the medium and upon the method which is employed in preparing them for observation.

As a result of his observations, he claims that these organisms are true yeasts, and accounts for their different forms by the differences produced by medium and fixation. The motile character of the organism has been mentioned by a number of investigators, but apparently no one has been able to discover the flagellum. By using undiluted, young peptone-glucose cultures, fixing in formalin and staining with Coerner-Fischer stain, the author was able to discern adhering to the capsule an exceedingly thin terminal flagellum about $2\ \mu$ long, bearing upon the distal end a tuft. The observation of the delicate filament is aided by the presence of this terminal tuft.

Attempts were made to prove the fixation of nitrogen with pure cultures in artificial media, but without success. In his investigations *Bacillus megatherium* was found to accompany the tubercle organism very frequently, and fixation experiments were tried with it without success.

Agricultural botany, J. PERCIVAL (*New York: Henry Holt & Co., 1900, pp. XII+798, figs. 265*).—This work on botany by the professor of botany of the South-eastern Agricultural College, Wye, England, is designed to meet the necessities of agricultural students. Much of the material found in the ordinary text-books is omitted and the matter arranged so as to not only cover the essentials of the science, but is applied to the crops of the farm, orchard, and garden. General morphology and physiology are treated at considerable length, the illustrations being drawn as far as possible from the well-known plants of the field and garden. Laboratory exercises are provided, in which the subjects for study are all drawn from common plants, the object being to secure familiarity with the structure and functions of the plants with which the agricultural student is most familiar. The classification and special botany of the principal farm crops of England are quite fully given, the material being grouped by natural orders. The botanical characteristics of the plants are described, their cultural varieties discussed, and notes given on their cultivation, handling, and uses. Under the Gramineæ special chapters are, in a similar manner, devoted to the true grasses, to cereals—in which oats, barley, rye, and wheat are considered—to the common grasses of the farm, and to the subject of grasses and clovers for temporary and permanent pastures. Special studies are also given of the weeds of the farm, farm seeds, fungi as related to farm crops, and bacteria as related to farm life, in every case the practical considerations being kept in the foreground.

Botany—an elementary text-book, L. H. BAILEY (*New York: The Macmillan Co., 1900, pp. XIV+355, figs. 502*).—This book is intended for the elementary student and in popular, though exact, language describes the nature of the plant, its relations with its surroundings, the minute structure of plants, and studies of the kinds of plants. The histological studies given are only those required for a proper understanding of the primary functions and actions of plants. The author does not believe in the extensive use of the compound microscope by the elementary student,

and has arranged the studies so as to secure familiarity with the things of everyday life. A feature of the work is its illustrations, which are nearly all new and well chosen to illustrate their respective topics.

The plant covering of Ocracoke Island, T. H. KEARNEY (*U. S. Dept. Agr., Division of Botany, Contributions from the U. S. National Herbarium, vol. 5, No. 5, pp. 261-319, figs. 18*).—An ecological study is given of the North Carolina strand vegetation as shown upon Ocracoke Island. The climate and physiography of the island and geology of its soils are described, together with the plant formations as exhibited in the strand flora, salt-marsh vegetation, pasture, and cultivated plants. The ecological forms and adaptations to environment of the different plants are discussed, and the anatomy of some of the more important species of the strand flora is figured and described.

Geographical distribution of the species of *Cuscuta* in North America, ALIDA M. CUNNINGHAM (*Proc. Indiana Acad. Sci., 1898, pp. 214, 215*).—Notes are given on the geographical distribution of the dodders into the different life zones as defined by Dr. C. H. Merriam, of this Department.

The absorption of water by decorticated stems, G. E. RIPLEY (*Proc. Indiana Acad. Sci., 1898, pp. 169-174*).—A number of experiments are reported in which the ability to take up water by stems which had had their cortex removed was compared with those in which the wood had been cut out, and both compared with normal stems. The experiments showed that the woody tissue is the principal path for the passage of water through stems, and the removing of the cortex delayed the wilting of the stems for some hours beyond that in which it took place in normal stems.

Transformations of organic substances during germination, G. ANDRÉ (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 11, pp. 728-730*).—From experiments, made chiefly on *Phaseolus*, it is concluded that the regeneration of insoluble albuminoids takes place at the expense both of asparagin and of the nitrogen of the amid acids. This is said to take place concurrently with the absorption of phosphoric acid by the plant. Starch and cellulose decrease progressively from germination until the time when the weight of the plant is greater than that of the seed, while the amount of cellulose not saccharized by dilute acids continually increases, this being due in a large degree to the transformation of starch.

FERMENTATION—BACTERIOLOGY.

Tobacco bacteria, C. J. KONING (*Indische Mercur, 1899, July 8; abs. in Jour. Roy. Micros. Soc. [London], 1900, No. 4, p. 501*).—According to investigations conducted by the author, *Diplococcus tabaci* and *Bacillus tabaci* I play an important part in the fermentation of tobacco. *B. tabaci* I is motionless, aerobic, and varies much in size in artificial cultures. It does not stain by Gram's method nor form spores. It is killed in 20 minutes at 60° C. and in 5 hours at 50°. Peculiar yeast-like appearances were observed in agar cultures some weeks old but on transference to fresh media normal growth returned. Asparagin is decomposed with the formation of ammonia, nitrates are reduced to nitrites, glucose consumed, and gelatin liquefied. On naturally acid tobacco extract the bacillus does not grow well, doing better when the acidity is diminished. *Diplococcus tabaci* forms small round yellow colonies on gelatin plates, grows best at room temperatures, and forms ammonia from asparagin. It is an essential aerobe and grows well on acid media. Gelatin is slowly and feebly liquefied by it.

Other bacteria were observed which are believed to have a share in raising the fermentation temperature and also connected with the fermentative processes.

Formation and structure of bacterial spores, MÜHLSCHGEL (*Centbl. Bakkt. u. Par.*, 2. Abt., 6 (1900), Nos. 3, pp. 65-71; 4, pp. 97-108).—Spore formation is said to be usually preceded by the appearance of globules in the protoplasm, after which toward one pole there appears a gray speck having approximately the same size as the future spore when the globules disappear. Spore formation is apparently brought about under the incentive of a nucleus, by the combination of the globules with the interstitial plasma. This may be demonstrated by staining reagents. The structural differentiation of the spore proceeds from within outward, ending in the formation of a membrane composed of 2 layers, the endosporium and the ectosporium. The difficulties frequently experienced in staining spores is said to be due in great measure to the resistance of the spore plasma and in a lesser degree to the membrane. The endosporium is stained with difficulty and may allow pigments to permeate it without its becoming affected. The endosporium is converted into the sheath of the young rod and the ectosporium is cast off during germination.

Studies in systematic bacteriology, F. D. CHESTER (*Delaware Sta. Rpt. 1899*, pp. 34-52).—The author has devoted considerable time in perfecting a method of bacterial investigation and in devising a scheme for bacterial description. The result of his labor is given in the report. The outline he proposes for the study of systematic bacteriology follows very closely the Migula system with few modifications. A number of terms are proposed and defined which the author thinks will prove useful in descriptive bacteriology. A proposed synopsis is given of the groups of bacteria, in which the groups of the genera *Bacterium*, *Bacillus*, *Pseudomonas*, *Microspira*, and *Mycobacterium* are distinguished.

Descriptions of certain species of bacteria isolated from cultivated soil, F. D. CHESTER (*Delaware Sta. Rpt. 1899*, pp. 52-75, pls. 2).—Descriptions of a number of soil bacteria are given, the following being described as new: *Bacterium fermentationis*, *B. radiatum*, *B. ambiguum*, *Bacillus delavariensis*, *B. soli*, and *Microspira tenuis*.

A key to species of bacteria, L. HEIM (*Abs. in Ztschr. Angew. Mikros.*, 6 (1900), No. 7, pp. 188-191).—Brief keys are given for the recognition of the more common species of *Streptococcus*, *Micrococcus*, *Sarcina*, *Bacterium*, *Bacillus*, and *Spirillum*.

Bacteria, A. RAMSEY (*Sci. Roll*, 1 (1900), No. 1, pp. 1-32).—A general bibliography of bacteriological literature is given. The topics are arranged chronologically and the entries in the present number cease with 1875.

Bacteria as friends and foes of the higher plants, T. M. FRIES (*Svenska Trädgårdssför. Tidskr.*, 1900, Nos. 1, pp. 3-6; 2, pp. 20-25).

On the structure of bacteria, FEINBERG (*Anat. Anzeiger*, 17 (1900), No. 12-14, pp. 225-237, pls. 5).—From studies of the bacilli of anthrax, tuberculosis, swine plague, and of other organisms, the author concludes that bacteria possess a differentiated plasma and nuclear structure.

Researches on nitrifying organisms, E. DEMOUSSY (*Ann. Agron.*, 26 (1900), No. 6, pp. 295-316).—Résumés are given of the following articles which appeared in *Arch. Sci. Biol. Russe* during 1899: On the culture of the nitrifying organisms of

the soil, by Oméliansky; The influence of organic substances on the activity of nitrifying microbes, by S. Winogradsky and V. Oméliansky; The influence of free carbon dioxid on nitrification, by Godlewski; and Nitrification of organic nitrogen, by V. Oméliansky, with comments on some of the articles by the abstractor.

Concerning the flagellæ, reserve material, nucleus, and spore formation of bacteria, A. MEYER (*Flora*, 86 (1900), pp. 428-468, pl. 1; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 10, pp. 339-341).

Do anaërobic organisms require oxygen? M. W. BEIJERINCK (*Arch. Neerland.*, 2. ser., 2 (1899), p. 397; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 10, p. 341).—The author states that obligate anaërobes as well as facultative ones require a small quantity of free oxygen for their maintenance.

A contribution to the knowledge of thermophilous bacteria, G. MICHAELIS (*Arch. Hyg.*, 36 (1899), p. 285; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 5, p. 154).—Four species of thermophilous bacteria were isolated from spring water whose optimum temperature for growth was between 50 and 60° C., with 57° the average. No growth takes place below 37° C. The organisms are spore forming, 2 to 4 μ in length. Their reaction toward various media, etc., are described.

Oxalic acid formation by bacteria, W. ZOPF (*Ber. Deut. Bot. Gesell.*, 18 (1900), No. 1, pp. 32-34, fig. 1).—The author reports the formation of oxalic acid from grape sugar in cultures of *Bacillus aceti*, *B. acetigenum*, *B. acetosum*, *B. ascendens*, *B. kützingerianum*, *B. pasteurianum* and *B. xylinum*. These bacteria were grown in a nutrient media containing 10 per cent gelatin, 1 per cent peptone, 1 per cent meat extract, with from 2 to 3 per cent grape sugar. Similar experiments were conducted with the same organisms in which the grape sugar was omitted from the nutrient solution and no oxalic acid was formed.

The physiology of *Bacillus prodigiosus*, G. RITTER (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 7, pp. 206-209).—A contribution to the knowledge of *B. prodigiosus* in which the behavior of the organisms in a number of media is described.

Bacterial studies in sugar manufacture, O. LAXA (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 9, pp. 286-295).

The fermentation of cellulose, V. OMELIANSKY (*Arch. Sci. Biol. [St. Petersburg]*, 7 (1899), No. 5, pp. 411-434).

Are bacteria the cause of tobacco fermentation? O. LOEW (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 4, pp. 108-112).—A controversial article in which the author maintains that tobacco fermentation is not bacterial.

Enzymes, J. GRÜSS (*Festsch. Schreudener, Berlin, 1899*, pp. 184-201, pl. 1; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 2, p. 223).—Notes are given on some of the properties of the enzyme of *Penicillium glaucum*. This enzyme is said to possess the power of energetically splitting up cane sugar, but has a less powerful action on starch and reserve cellulose and has none of the properties of oxidase. Malt, on the other hand, has the action of γ -oxidase. It acts energetically on starch, less so on cane sugar, and very slightly on reserve cellulose.

A proteolytic enzyme in germinating seeds, V. HARLAY (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 16, pp. 623-626).—The presence of a proteolytic ferment in fungi has been previously noted by Bourquelot and Hérissé (E. S. R., 10, p. 929). In the present paper the author gives a report of experiments made with germinating lentils, in which he found a proteolytic ferment analogous to trypsin. It is believed that such a ferment will be found in all germinating seeds. The ferment found in the lentil seeds seems to be identical with that reported above in the fungi.

An enzyme causing cleavage of protein in germinating barley, W. WINDISCH and B. SCHELLHORN (*Wehnschr. Brau.*, 17 (1900), No. 24, pp. 334-336).

A proteolytic diastase of malt, A. FERNBACH and L. HUBERT (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 26, pp. 1783-1785).—An account is given of the

isolation of a proteolytic diastase from barley malt, and some of its properties are described.

The influence of phosphates and other mineral substances on the proteolytic diastase of malt, A. FERNBACH and L. HUBERT (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 4, pp. 293-295).

METEOROLOGY.

Atmospheric radiation, F. W. VERY (*U. S. Dept. Agr., Weather Bureau Bul. G*, pp. 134, figs. 22).—This paper gives the results of investigations carried on during the past 8 years to determine the law of radiation as dependent upon pressure or density of the air. The apparatus and methods used are described in detail, and the results of studies of the influence of various conditions upon radiation are reported.

“The results of the present research prove that within moderate depths of only a few meters the radiation of dry air, purified from carbon dioxide, increases quite uniformly with the depth; that the radiation of a 1-meter layer of purified air at 50° C. and near atmospheric pressure (735 mm.), as compared with one at 0° C., is 0.00068 radim, representing a transformation and transfer of thermal energy of 0.00068 small calories every second through each square centimeter of limiting surface; that the radiation of a like depth of carbon dioxide at the same temperature is three and one-half times that of air, or 0.00238 radim, which is very nearly a maximum for this temperature, further increase of the radiant depth being unattended by a corresponding addition of radiant energy, showing that equilibrium between radiation and emission has been almost reached at this depth; that the radiation from a layer of steam 5 ft. deep at one-sixth of atmospheric pressure is two and one-half times that from a like body of dry air at temperatures near the boiling point of water, and eight-tenths of the radiant emission from the black solid body; while for smaller depths the radiant power of water vapor is relatively greater, a steam jet of small dimensions radiating over four times as strongly as one of air, a ratio which would doubtless have been considerably greater if the air had been perfectly dry.

“There appears to be no reason to doubt that the radiation of a moderate depth of homogeneous air at a given temperature depends on the product of the depth by the density, and remains the same when depth and density vary inversely; but the absorption of a given mass of aqueous vapor has been found to be smaller when distributed through a large volume of air than when concentrated. The phenomena are conditioned by molecular relations. Reciprocal variation of depth and density does not change the number of molecules which are engaged in the radiant transaction in a homogeneous medium; but dilution by another substance involves a partition of energy among molecules whose radiant and absorbent properties are dissimilar.

“As an absorbent of terrestrial radiation aqueous vapor is very much more efficient than any other atmospheric ingredient; but as radiators when in large masses, the substances which compose the atmosphere do not differ as widely as might be supposed, and the position of chief radiant may be assumed in turn by either aqueous vapor, carbon dioxide, or the permanent gases, according as the depths and temperatures of the emissive and absorbent layers change. The depth of gas which gives maximum radiation at short range is an insignificant quantity compared with atmospheric dimensions, and radiation from either the atmosphere of the earth or the solar chromosphere is a superficial phenomenon, even when the masses of heated gas measure thousands of miles in thickness. The fineness of the chromospheric lines in the solar spectrum, although the shifts of the Fraunhofer lines indicate pressures of

many atmospheres at the base of the chromosphere, is a sufficient demonstration that only the outer layers radiate. If the emission proceeded also from the depths of the chromospheric mass, the lines of hydrogen and some other elements would be greatly widened; and if the earth's atmosphere radiated unimpeded throughout its depth, its thermal changes and its radiant effects would be enormous. Instead of this, we find the atmosphere playing the part of a conservator of thermal energy, and must gratefully admire the beneficent arrangement which permits the earth to be clothed with verdure and abundant life."

On solar changes of temperature and variations in rainfall in the region surrounding the Indian Ocean. N. and W. J. S. LOCKYER (*Nature*, 63 (1900), Nos. 1622, pp. 107-109; 1623, pp. 128-133, figs. 3; *Proc. Roy. Soc. [London]*, 67 (1901), No. 440, pp. 409-431, figs. 3).—A study of the chemical origin of spectrum lines most evidenced in sun spots at the maxima and minima periods and of the rainfall of India, Mauritius, and other regions is reported. The conclusion is reached "that there is a considerable rise above the mean temperature of the sun around the year of sun-spot maximum and a considerable fall around the year of sun-spot minimum." An analysis of the data relating to rainfall in India during the southwest monsoon and in Mauritius showed that the largest amount of rain fell in India at sun-spot maximum and in Mauritius at sun-spot minimum, although the maximum rainfall in Mauritius generally gave rise to a secondary maximum in India, which therefore "has two pulses of rainfall, one near the maximum and the other near the minimum of the sun-spot period." All famines in India during the last 50 years and all periods between 1849 and 1878, when the Nile was lowest, occurred in the intervals between these two "pulses".

Report of the meteorologist, W. H. BISHOP (*Delaware Sta. Rpt. 1899*, pp. 180-193).—Monthly summaries of observations at 6 different places in Delaware on temperature, pressure, precipitation, relative humidity, and prevailing winds during the year ended June 30, 1899, and a summary of observations on temperature and precipitation during the calendar year 1898 are given.

The summary for 1898 is as follows:

Annual summary of meteorological observations in Delaware, 1898.

Locality.	Temperature.			Total rainfall.	No. days on which 0.01 in. or more of rain fell.
	Highest.	Lowest.	Mean.		
	Deg. F.	Deg. F.	Deg. F.	Inches.	
Newark	98 (July)	0.4 (Feb.)	52.9	50.62	103
Middletown	102 (July)	5 (Feb.)	54	51.02	97
Dover	99 (July)	6 (Feb.)	54.3	42.20	98
Milford	99 (July)	10 (Feb.)	56.8	42.06	93
Seaford	98 (July)	11 (Feb.)	55.5	43.84	95
Millsboro	98.5 (July)	6 (Dec.)	54.7	48.50	119

Report of the meteorologist, N. HELME (*Rhode Island Sta. Rpt. 1899*, pp. 199-209).—This includes general notes on the weather and a

tabulated record of observations at Kingston on temperature, precipitation, cloudiness, and prevailing winds during each of the first six months of 1899, with a summary for the period from January 1, 1890, to June 30, 1899, inclusive. The summary for 6 months of 1899 (January 1 to June 30, inclusive) is as follows:

Temperature (degrees F.).—Maximum, 95, June 6; minimum, -10, February 10; highest monthly mean, 67.4, June; lowest monthly mean, 23.5, February; highest daily mean, 80, June 6; lowest daily mean, -1.5, February 10; range for six months 105. *Precipitation* (inches).—Total (rain and melted snow), 26.79; greatest monthly, 9.67, March; least monthly, 1.87, June; greatest in 24 consecutive hours, 2.76, March 19; snow fall—total, 34.25; greatest monthly, 24.5, February; least monthly, 0.5, April. *Weather*.—Number of clear days, 77; number of fair days, 44; number of cloudy days, 60; number of days on which there was precipitation of 0.01 in. or more, 59. *Prevailing wind*, southwest.

The rainfall in May was the smallest recorded at Kingston during the 11 years that records have been kept.

On the study of distant storms by means of the electradiophone, T. TOMMASINA (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 22, pp. 876-878).

Seasonal variations in temperature at various altitudes in the free atmosphere, L. TEISSERENC DE BORT (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 22, pp. 920-922, fig. 1).—The results of observations on temperature in different seasons of the year by means of balloons are charted and discussed. These show that there is a very marked seasonal variation in temperature up to an altitude of 10,000 meters, the variation diminishing as the height increases.

On the gaseous projectiles of cannon proposed for the prevention of the formation of hail, G. GASTINE and V. VERMOREL (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 19, pp. 766-768).—Various forms are discussed, those producing annular motions of the air when discharged being considered most effective.

Temperature at the experimental farm at Wollonbar, New South Wales (*Rpt. Under Sect. Mines and Agr., New South Wales*, 1899, pp. 39, 40).—A tabular statement of maximum and minimum temperatures, rainfall, and number of cloudy and dry days during each month of 1899.

Meteorological observations at Hawkesbury Agricultural College, Richmond, New South Wales (*Rpt. Under Sect. Mines and Agr., New South Wales*, 1899, p. 15).—A tabular record is given of the rainfall and highest, lowest, and mean temperatures during each month of the years 1893 to 1899; evaporation for each month of 1898 and 1899; and velocity of the wind during parts of 1898 and 1899.

Actinometric measurements in the Pamirs, B. W. STANKEWITCH (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 22, pp. 879, 880).

WATER—SOILS.

Third report of work in the study of the fertility of soils, S. BOGDANOV (*Selsk. Khoz. i Lyesor.*, 198 (1900), July, pp. 59-112; Aug., pp. 241-288).—This is a continuation of previous work (E. S. R., 11, p. 130). The author elaborated some years ago a method of determining the fertility of a soil on the basis of a simplified chemical analysis. The method has been put to repeated tests in the course of several years and proved reliable in every instance. The chief features

of the method are as follows: The soil containing a medium amount of moisture is placed in a thermostat for 48 hours at 30° C., and nitrogen in the form of ammonia and nitric acid is determined. The results thus obtained are assumed to indicate the amount of nitrogen assimilable by oats (the cereal with which the author chiefly experimented). The phosphoric acid is then determined in a solution obtained by digesting the soil for 24 hours with a 2 per cent solution of acetic acid, using the soil and solution in the ratio of 1:4. This gives the available phosphoric acid. All other assimilable substances are determined by analyzing an aqueous solution obtained by shaking for 48 hours 1 part of the soil with 100 parts of water. The results thus obtained serve as a guide in determining the fertilizer needs of a soil. Culture experiments made on the basis of such results corroborated the correctness of the judgment based on them. In the present report, which covers the years 1898 and 1899, experiments are described which were instituted to subject the author's method to further tests. Many new soils from various localities in Russia were studied. Not only oats, but also barley, millet, peas, flax, buckwheat, mustard, and sugar beets were grown. In all cases the kind of fertilizer required was reliably indicated by the chemical analysis.

The results of numerous culture experiments to determine the easily assimilable substances in soils of different degrees of fertility carried out during several years are reported. A yield of oats on 2 kg. of soil of less than 2 gm. of dry grain and 6 to 7 gm. of dry crop above the ground is considered low; 3 to 4 gm. of dry grain and 6 to 12 gm. of dry crop above ground, medium; over 4 gm. of dry grain and over 12 gm. of dry crop above the ground, high. The following table gives the mean of the author's figures for easily assimilable fertilizing constituents in the soil corresponding to different yields of oats and also Hellriegel's figures for nitrogen:

Assimilable plant food in the soil corresponding with different yields of oats.

	Author's data.			Hellriegel's figures for nitrogen.
	Potash.	Phosphoric acid.	Nitrogen.	
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Low yield.....	0.001	0.001	0.003	0.002
Medium yield.....	.002	.002	.007	.005
High yield.....	.003	.003	.011	.008

Experiments with barley were more limited than with oats. The author concludes, however, that the nitrogen content of the soil corresponding to a medium yield of barley is 0.0051 to 0.0083 per cent. Hellriegel's figure is 0.0042 to 0.0070 per cent.

Experiments with sugar beets gave the following results:

Assimilable plant food in the soil corresponding with different yields of sugar beets.

	Nitrogen.	Phosphoric acid.
	<i>Per cent.</i>	<i>Per cent.</i>
High yield.....	0.0140	
Medium yield.....	.0069	0.0026
Low yield.....		.0008

Experiments with white mustard showed that, while it resembles oats and barley with respect to assimilating nitrogen and phosphoric acid from the soil, it is strikingly sensitive to the sulphuric acid content of the soil. Other things being equal, the yield was increased $1\frac{1}{2}$ to 2 times when a fertilizer containing sulphuric acid was added.

From his own results and from those of Hellriegel, the author has prepared the following table, which indicates the contents of easily assimilable substances in the soil in the cases of low, medium, and high yields of oats and other plants which do not differ strikingly from one another in their plant-food requirements:

Assimilable plant food in the soil¹ corresponding with different yields of oats and plants of similar requirements.

	Nitrogen.	Phosphoric acid.	Potash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
High yield.....	0.0108	0.0050	0.0060
Medium yield.....	.0060	.0022	.0020
Low yield.....	.0021	.0010	.0010

—P. FIREMAN.

The amount of humus in soils and the percentage of nitrogen in the humus as affected by applications of air-slaked lime and certain other substances, H. J. WHEELER, C. L. SARGENT, and B. L. HARTWELL (*Rhode Island Sta. Rpt. 1899, pp. 152-159*).—This is an account of studies of the changes in humus and nitrogen content of soil which had been used in pot experiments with corn, oats, and rye during 1893, 1894, and 1895. Humus was determined by treatment with hydrochloric acid according to Hilgard, followed by extraction with ammonia according to Huston and McBride's method.

“The nitrogen in the humus was determined by using a $2\frac{1}{2}$ per cent solution of potassium hydroxid in place of the solution of ammonium hydroxid of like strength, which was employed in the determination of humus. Aliquot portions of the extract were then neutralized with sulphuric acid, and after evaporating to dryness in a Kjeldahl flask, the nitrogen was determined as usual by the method of Kjeldahl. The soils were air-dried before analyzing, and the different samples contained from 2.00 to 2.75 per cent of water determined at 100° C.”

¹ Calculated to dry matter.

At the beginning of the pot experiments with the soil used in this investigation muriate of potash was applied at the rate of 7.36 gm. and dissolved boneblack at the rate of 22.07 gm. per pot in every case. These amounts were afterwards increased to 10 and 25 gm. respectively. In different cases ammonium sulphate and nitrate of soda were applied in amounts furnishing 2.65 gm. of nitrogen per pot. Where lime was used the maximum amount applied was 147.2 gm. per pot (4 tons per acre). Gypsum was also applied in some cases at rates furnishing the same amount of calcium oxid as the lime. The results of the determinations of humus and nitrogen are given in the following table:

The influence of lime and other substances on the humus and nitrogen content of soils.

Fertilization.	Humus nitrogen in dry soil.	Humus in dry soil.	Nitrogen in dry humus.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Unmanured	0.130	3.86	3.37
Ammonium sulphate128	3.93	3.26
Ammonium sulphate, air-slaked lime (1 ton per acre)133	3.77	3.53
Ammonium sulphate, air-slaked lime (4 tons per acre)126	3.63	3.47
Ammonium sulphate, calcium sulphate (land plaster) at rate equivalent in CaO to 4 tons of air-slaked lime per acre139	3.65	3.81
Without nitrogen and lime129	3.75	3.44
Air-slaked lime (4 tons per acre)139	3.51	3.68
Nitrate of soda143	3.93	3.64
Nitrate of soda and air-slaked lime (4 tons per acre)133	3.42	3.89

"From the foregoing it will be seen that without exception the addition of air-slaked lime or gypsum resulted in lowering the total amount of humus, as compared with the unmanured plat, yet in every instance the percentage of nitrogen in the humus had been increased. In fact, the latter statement applies also even where no nitrogen was added.

"Where lime was not applied, but nitrogen was employed in form of sulphate of ammonia, which in the acid soil proved poisonous to plants, it will be observed that the percentage of nitrogen in the humus was even less than where no manure was used. On the contrary, where nitrogen in the form of nitrate of soda was added without lime, the percentage of nitrogen in the humus was greater than in the case of the unmanured soil.

"It is also of special interest to observe that in the case of the unlimed soil which received potash and phosphoric acid but no nitrogen, the percentage of humus became less than in the unmanured soil; while, on the contrary, where nitrogen was applied as nitrate of soda and as sulphate of ammonia to unlimed soil, it is possible that a slight increase in the percentage of humus resulted. The differences are not great enough, however, to furnish any positive evidence in this respect."

The causes and the importance of the decomposition of nitrates in soils, W. KRÜGER and W. SCHNEIDEWIND (*Landw. Jahrb.*, 29 (1900), No. 4-5, pp. 747-770, pls. 2).—In continuation of previous investigations, the authors report pot experiments to determine the action of various kinds of carbonaceous materials and the effect of well-rotted and fresh mixtures of manure and litter on the activity of the denitrifying organisms, as well as field experiments on denitrification, comparing the results by the 2 methods, and discussing the influ-

ence of the previous handling of the manure on its subsequent behavior in the soil.

Of the various carbonaceous substances tested (pentosans and crude fiber from wheat straw, cotton, straw, peat, and pentosans from peat) the first was most active in promoting denitrification and decreasing the yield.

The application of sterile fresh manure resulted in no increase of yield, while well-rotted manure produced a decided increase. In the field experiments, also, it was found that the use of fresh manure resulted in a decided decomposition or transformation of the nitrogenous compounds of nitrate of soda or of urine. On the plats receiving applications of a mixture of solid and liquid cow manure with straw there was a yield of 825 lbs. less of dry matter and 61.36 lbs. less of nitrogen than on the plats receiving only liquid manure (urine). While the results of the field experiments agree in this case with those of the pot experiments in showing that there is an important decomposition or transformation of nitrates under certain conditions of manuring, it is not considered safe to make too close an application of the results of pot experiments in field practice.

The chemical functions of certain soil bacteria, F. D. CHESTER (*Delaware Sta. Rpt. 1899, pp. 76-85, figs. 3*).—This article records observations on the production of ammonia and the reduction of nitrates to nitrites by soil bacteria and on the relation of the growth of these organisms to the reaction of the media.

The apparatus used in studying the production of ammonia in neutral bouillon and for determining the amount of ammonia produced are described. The following table gives the amounts of ammonia in milligrams per 100 cc. of culture produced by the different organisms studied during 7, 14, and 30 days' growth at room temperature:

Ammonia found in cultures of soil organisms in neutral bouillon.

Name of species.	Amount per 100 cc. of culture.		
	7 days.	14 days.	30 days.
	<i>Mg.</i>	<i>Mg.</i>	<i>Mg.</i>
<i>Bacterium mycoides</i>	9.18	20.06	45.50
<i>Bacillus subtilis</i>	6.46	18.35	46.20

<i>Bacillus 7</i>	2.40	19.72	38.10
<i>Microspira tenuis</i>	0	0	0
<i>Bacterium fermentationis</i>	0.30	8.50	27.90

The bouillon used in these cultures contained 1.11 per cent of organic matter and 0.18 per cent of nitrogen. "The largest quantities of ammonia produced after 30 days' growth was for *Bacterium mycoides* and *Bacillus subtilis*, 45.5 and 46.2 mg. per 100 cc. respectively. In

other words, only about two-tenths of the total nitrogen in the medium was converted into ammonia."

The ammonia produced was determined by distilling with calcined magnesia. It was found that the uninoculated bouillon gave 3.4 mg. of ammonia per 100 cc. by this treatment, and consequently this correction was made in the results obtained with the different cultures.

To determine the effect of an abundant supply of air upon the denitrifying action of soil bacteria *Bacillus pulvinatus* was grown in peptone solution containing 0.1 gm. of nitrate of soda per liter in a flask abundantly supplied with purified sterile air and also in a flask without aeration. "At the end of 5 days 7 mg. of nitrite of soda per 100 cc. were found in the aerated culture and 30 mg. in the nonaerated. At the end of 10 days 20 mg. of nitrite of soda were found in the aerated and 40 mg. in the nonaerated culture."

The denitrifying action of a number of soil organisms was studied. The various organisms were grown in a neutral 1 per cent Witte peptone broth containing 0.1 gm. of nitrate of soda per liter, in Erlenmeyer flasks plugged with cotton wool and kept at room temperatures. Nitrite was determined by the Griess colorimetric method. The results were as follows:

Nitrite in cultures of soil bacteria.

Name of species.	Amount of nitrite of soda in 100 cc. of culture.				Nitrates in culture at end of 30 days; tested with diphenylamine.
	5 days' growth.	10 days' growth.	15 days' growth.	30 days' growth.	
	Mg.	Mg.	Mg.	Mg.	Mg.

The organisms studied were found to grow best in neutral or slightly alkaline media. In media containing carbohydrates the organisms produced considerable amounts of acid, including acetic, formic, propionic, butyric, and lactic acids. "All soils containing larger or smaller quantities of vegetable matter are liberally supplied with carbohydrates in one form or another, hence all soils have a tendency to become acid as a result of the development of soil microbes."

The following table shows the amounts of free acid stated in the number of cubic centimeters of tenth-normal sodium hydroxid re-

quired to neutralize 100 cc. of the culture produced by various soil organisms during different periods of growth.

Free acid in cultures of different soil organisms stated in cubic centimeters of tenth-normal sodium hydroxid required to neutralize 100 cc. of the cultures.

Name of species.	In 2 per cent glucose bouillon; 5 days' growth; direct titration for free acid.	In 2 per cent peptone broth, with an excess of chalk; 4 weeks' growth; by distillation.	In 4 per cent glucose bouillon, with an excess of chalk; 4 weeks' growth; by distillation.	In 2 per cent glucose bouillon; 5 days' growth; direct titration for free acid.

Composition of the air at various altitudes, G. HINRICHS (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), pp. 442, 443; *abs. in Jour. Chem. Soc. [London]*, 78 (1900), No. 456, II, p. 649).—Reports calculations of the proportions of carbon dioxide, oxygen, argon, nitrogen, and hydrogen at different altitudes.

The regeneration of confined air by means of sodium dioxid, G. F. JAUBERT (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 18, pp. 715, 716).—This is a brief note referring to the proposition of Desgrez and Balthazard (see below) to use sodium dioxid to purify air vitiated by respiration, and calling attention to the work of the author on this subject during the past 3 years. The principal objection urged to the use of sodium dioxid for this purpose is its high price.

The regeneration of confined air by means of sodium dioxid, DESGREZ and BALTHAZARD (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 20, p. 812).—A reply to the above referring to previous communications¹ and denying Jaubert's claim to priority.

Well waters—a study, A. MCGILL (*Trans. Ottawa Lit. and Sci. Soc.*, 1899–1900, No. 2, pp. 133–148, figs. 4).—This article discusses the origin and movement of ground water, the origin and sources of contamination of well waters, and means of detecting and preventing such contamination.

On the presence of oxysulphocarbonates of iron in the water of the Rhone, H. CATSSE (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 23, pp. 947–949).

Underground temperature at Oxford in the year 1899 as determined by five platinum resistance thermometers, A. A. RAMBANT (*Proc. Roy. Soc. [London]*, 67 (1900), No. 437, pp. 218–222).—Observations with thermometers of the Callendar and Griffiths² pattern at depths of 6½ in., 1 ft. 6 in., 3 ft. 6½ in., 5 ft. 8½ in., and 9 ft. 11½ in. are very briefly reported and discussed and the method of standardizing the apparatus is described. A comparison is made of the calculated and observed results which seem to indicate a high degree of precision in the observations.

¹ *Compt. Rend. Acad. Sci. Paris*, 128 (1899), pp. 361–363; 131 (1900), No. 7, pp. 429–431.

² *Nature*, 53 (1895), pp. 39–46, figs. 4.

Humus in soils, G. D'UTRA (*Bol. Agr. São Paulo*, 1. ser., 1900, No. 3, pp. 152-160).—Analyses of 146 samples of soil from different parts of São Paulo, Brazil, showing moisture, organic matter, phosphoric acid, lime, potash, nitrogen, and humus are reported and discussed. The humus varied from 0.024 to 3.11 per cent, the nitrogen from 0.002 to 0.38 per cent, potash from 0.01 to 0.59 per cent, phosphoric acid from trace to 0.36 per cent, and lime from trace to 0.80 per cent. The soils are generally deficient in humus. The percentage of nitrogen in humus showed wide variations.

On certain conditions affecting the nitrification of soils, J. NEISH (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 11, pp. 645-651).—A popular discussion of this subject, emphasizing particularly the importance of thorough tillage as a direct means of promoting nitrification.

Further observations upon the need of lime in Rhode Island soils, H. J. WHEELER and G. E. ADAMS (*Rhode Island Sta. Rpt.* 1899, pp. 160-162).—A brief account is given of 4 cooperative experiments on grasses conducted for the purpose of further studying the lime requirements of Rhode Island soils. "The results obtained in 1899 fully corroborate those of previous years (E. S. R., 11, p. 918), and together they indicate that a need of lime is quite general in Rhode Island soils."

Preliminary analytical studies of the soils of the Province of Bari, Italy, G. D'ADDIEGO (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 1, pp. 19-44).—This article includes a classification of the soils of this province, descriptions of samples analyzed and of analytical methods employed, chemical analyses of 9 samples, and general conclusions and practical applications of the results.

Soil exhaustion, G. E. STONE (*Massachusetts State Bd. Agr. Bul.* 6, pp. 29-36, figs. 3).—Notes are given on some of the causes of soil exhaustion in Massachusetts, and suggestions are made for its restoration.

The future of desert countries, A. SOULEYRE (*Rev. Sci. Paris*, 4. ser., 14 (1900), Nos. 18, pp. 545-560, figs. 3; 22, pp. 681-688; 24, pp. 743-749).

The weathering and erosion of north and south slopes, G. CULBERTSON (*Proc. Indiana Acad. Sci.*, 1899, pp. 167-170, fig. 1).—Examinations of the slopes of a number of ravines indicate a decided variation in the rate of weathering when the valleys trend from east and west to southeast and northwest approximately, but little difference where the valleys trend approximately north and south. The differences are doubtless due to greater expansion and contraction, and alternate thawing and freezing on the slopes with southern exposure.

The physical geography of the region of the great bend of the Wabash, W. A. MCBETH (*Proc. Indiana Acad. Sci.*, 1899, pp. 157-161, figs. 3, map 1).—Discusses the glacial action in this area.

Studies on the formation of loess, TUTKOWSKI (*Scottish Geogr. Mag.*, 16 (1900), No. 3, pp. 171-174; *abs. in Bul. Soc. Belge Geol.*, 14 (1900), No. 3, p. 180).—This is a discussion, based on geological and soil studies in Russia, of Richthofen's theory of the formation of loess during interglacial or post-glacial periods. The author advances the theory that the formation of loess soils is due to the desiccating and transporting action of the foehn. He considers as normal loess soils only those which are found in European Russia, North America, and China. The formation of the so-called loess of France and Belgium he believes to be due to other agencies.

Iowa geological survey, S. CALVIN and H. F. BAIN (*Ann. Rpt. Iowa Geol. Survey*, 10 (1899), pp. 666, pls. 11, figs. 102, maps 10).—This contains, besides administrative reports, papers on Statistics of mineral production of Iowa in 1899, by S. W. Beyer; The succession of fossil faunas in the Kinderhook beds of Burlington, Iowa, by S. Weller; Geology of Lyon and Sioux counties, by F. A. Wilder; The flora of Lyon County, by B. Shimek; Geology of Osceola and Dickinson counties, by T. H. MacBride; Geology of Hardin County, by S. W. Beyer; Geology of Worth County, by I. A. Williams; Geology of Dubuque County, by S. Calvin and H. F. Bain; and

Forestry notes for Dubuque County, by T. H. MacBride. The articles on the geology of the different counties deal with location, previous geological work, physiography, stratigraphy, and economic geology, including mineral products, water supply, and soils. Special attention is given to the loess and glacial drift soils of the Pleistocene deposits of the different counties.

FERTILIZERS.

On the question of the preservation of manure and urine, J. KÖNIG (*Vrtljschr. Bayer. Landw. Raths.*, 5 (1900), *Sup. No. 3*, pp. 500-510).—The author briefly reviews the work of other investigators on this subject and reports observations on the losses of nitrogen in form of ammonia from solutions of ammonia, ammonium carbonate, ammonium sulphate, and urine with and without access of air, and with and without addition of phenol. The conclusion is reached that the main precaution to be observed in preserving manure from loss of nitrogen is to exclude the air. Unless the air is excluded, preservative materials are of little value. The following practical rule, which is shown to rest on a scientific basis, is given: Protect the manure and urine from air, sun, and rain, and apply in well-rotted condition to soils kept open and well aerated by marling or liming.

The method of making manure-preservation experiments, T. PFEIFFER, F. MOSZEIK, and O. LEMMERMAN (*Landw. Vers. Stat.*, 54 (1900), *No. 5-6*, pp. 349-378).—The errors incident to such experiments and means of overcoming them are discussed, the methods used by the authors are described, and a series of experiments are reported.

The contradictory results often obtained in laboratory experiments on the preservation of manure are ascribed to the use of inaccurate or dissimilar methods. Moreover, the results obtained in such experiments can not be applied in practice without danger of serious error. The authors have undertaken to devise a system of investigation which reduces as far as possible the sources of error and makes the results of more scientific and practical value. As a check on the determinations of nitrogen at different stages they recommend the determination of the income in food and outgo in excrement and animal product of the nitrogen, phosphoric acid, and potash. The study of the losses of nitrogen must begin in the stall. Contradictory results have frequently been due to variations in the amount of the easily and difficultly decomposable nitrogen compounds. The difficulties pointed out by Holdefleiss (*E. S. R.*, 11, p. 32) regarding the taking of samples, correction for uneaten food, etc., may be overcome by the use of the balance of nitrogen and mineral matter referred to above. As Maercker has shown, the preservation experiments should always be accompanied by fertilizer experiments.

Experiments with 8 cows in two 14-day series are reported. In one series the manure remained under the animals 8 days, in the other only

24 hours, the manure for each series being kept separate. The liquid excrement was weighed and examined daily. The precautions observed in the sampling of the feed and litter; the construction of the stalls, manure heaps, and liquid manure pits; the weighing and sampling of the solid and liquid manure; the determination of the milk production and increase in live weight; and the analytical methods used are described. The balance for the first and second periods gave a loss of 8.3 per cent of nitrogen, a gain of 2.7 per cent of phosphoric acid, and no change in the amount of potash. The balance for the heaps of mixed solid and liquid manure (after an average of 107 days) showed a loss of 19.1 per cent of nitrogen, and an increase of 3.6 per cent of phosphoric acid and 0.8 per cent of potash. The results obtained indicate the reliability of the methods used, but investigations with a view to their improvement are to be continued.

Denitrification and the action of barnyard manure, T. PFEIFFER and O. LEMMERMANN (*Landw. Vers. Stat.*, 54 (1900), No. 5-6, pp. 386-462).—From the results of an extended series of experiments in pots and on plats in continuation of those previously reported (E. S. R., 11, p. 134) the following conclusions are drawn: The utilization of the nitrogen supply of the soil is unfavorably influenced both by an increase of organic matter and of denitrifying organisms. By the addition of barnyard manure denitrification is promoted, both by the organic matter and by the bacteria, which are thus supplied to the soil. The injurious effects noted in pots during the first season disappear during the second. An increase of organic matter by the addition of a solution of calcium citrate, as well as the use of a pure culture of denitrifying organisms, resulted in the evolution of free nitrogen. The loss of nitrogen in the free state as a result of the application of barnyard manure in pot experiments is considered of only secondary importance in comparison with other factors influencing the utilization of nitrogen by the crop. The utilization of applications of nitrate of soda on light, sandy soils is seriously interfered with by applications of cattle or horse manure at rates of 800 metric centners per hectare (17.81 tons per acre). Since the same manure gives very different results in pots and on plats, the authors caution against the direct application of the results of pot experiments with manure in actual practice. The variable action of the nitrogen of manure can not be explained by ordinary analyses, in which the contents of ammoniacal, amid, and digestible proteid nitrogen are determined. It is claimed that the variable action of different kinds of manure is explained by variations in the extent of denitrification. In the authors' experiments no relation was found to exist between the content of nitrogen-free organic substances, particularly pentosans, and the action of the nitrogen. There is wide difference in the ease and rapidity with which the nitrogen compounds of different kinds of manure undergo decomposition, and in the authors' opinion this is one

of the main causes of the variations in the action of the nitrogen. When the conditions in the preparation of the manure are such as to result in the removal of a large part of the nitrogen-free organic matter, the transformation of the nitrogen into forms which are readily assimilable by plants is almost entirely prevented. Neither ammonia nor elementary nitrogen is formed, and even amids are formed from proteid nitrogen to a very limited extent. An important after-effect of the nitrogen of manure was noted. A part of the nitrate nitrogen, in case of applications of manure, is fixed, and may result in a direct increase in the utilization of nitrogen or may exert an after-effect in increasing the yield of the succeeding crop. The theory of Gerlach that there are certain kinds of manure which produce more nitrates than they destroy, and thus do not cause a loss of the nitrogen of nitrates used in connection with the manure, is not substantiated by the authors' experiments.

The fifth year's observations upon the effectiveness of nitrate of potash, as compared with like amounts of nitrogen and potash in form of muriate of potash and nitrate of soda, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1899, pp. 174-176*).—The experiments of previous years (E. S. R., 11, p. 914) on this subject were continued during 1899. The results obtained are briefly summarized in this article.

"The data for the 5 years since this experiment was begun show as yet no striking differences between the results with nitrate of potash and those secured with like quantities of nitrogen and potash as nitrate of soda and muriate of potash. It is evident, therefore, that with the amounts of nitrogen and potash employed neither the chlorin nor the soda has as yet proved of positive advantage either as a direct or indirect manure. Incidentally, the experiment has shown the inferiority of gypsum (land plaster) as a source of lime for a sour soil, as compared with air-slaked lime."

Observations upon the growth of plants on an acid upland soil, limed and unlimed, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul. 69, pp. 177-204, figs. 7*).—This is an account of a continuation during 1899 of observations which were begun in 1893 (E. S. R., 11, p. 915). During this period nearly 200 different kinds of plants have been tested. No lime has been applied since 1894. The kinds and amounts of other fertilizers used in 1899 were the same as in the previous year. Data for growth and yield of crops on the different plats are reported in detail. The principal results may be summarized as follows:

Plants benefited by liming.—Orange quince, black Tartarian cherry, early Richmond cherry, Burbank Japan plum, American linden, American elm, rhubarb, Australian saltbush, hemp, asparagus, red raspberry (Cuthbert), red and white currants, barley, oats, spring wheat, mangel-wurzels, chicory, onions, English turnips, sweet peas, balsams, and poppy.

Plants not benefited by liming.—Norway spruce, cranberry, cowpea, and flax.

Plants giving inconclusive results with liming.—Concord grapes, blackberry, raspberry (Ohio Blackcap), spring rye, serradella, and carrots.

Of the plants tested the following were more benefited by nitrate of soda than by sulphate of ammonia: Rhubarb (on limed plats), Australian saltbush, hemp, asparagus, currants, serradella, mangel-wurzels, onions, English turnips, sweet peas, balsams, and poppy. The plants on which sulphate of ammonia proved superior to nitrate of soda were blackberry, raspberry, cowpea, chicory, and flax.

“As a result of the observations thus far made here, it may be said of wheat, as of barley, oats, and rye, that no regularly recurring advantage of nitrogen in nitrate of soda, as compared with nitrogen in sulphate of ammonia, has been observed.” In case of carrots results were inconclusive.

Investigations on losses from manure heaps by soaking into the soil beneath. P. RIPPERT (*Fühling's Landw. Ztg.*, 49 (1900), No. 22, pp. 829-835, fig. 1).—Examinations of the soil under manure pits lined in various ways and unlined showed the presence of large amounts of nitrogen compounds which had leached from the manure. There were also present large numbers of various kinds of organisms which transform nitrogen compounds and facilitate their escape in the drainage. The construction of pits which will not be subject to such losses is discussed.

Examination of soil to different depths underneath manure heaps. A. EMMERLING and H. WEHNERT (*Landw. Wchnbl. Schleswig-Holstein*, 49 (1899), No. 49, pp. 904-908).—Investigations similar to those noted above, except that no study was made of the organisms present.

The fertilizer and phosphate industry. L. P. BROWN (*Tradesman*, 44 (1901), No. 9, pp. 92-97).—It is estimated that there is at least \$100,000,000 invested in the United States in plants confining themselves strictly to the manufacture of artificial fertilizers.

“When to this are added the large sums invested in phosphate mines in Florida, Tennessee, and South Carolina, in pyrite mines in Virginia and Vermont, and in the plants for recovering animal ammoniates at packing houses in Chicago, Kansas City, Omaha, etc., in the cotton-seed oil mills, and in independent sulphuric acid plants, selling their products mainly to manufacturers of fertilizers, it would seem that \$300,000,000 would be a low estimate at which to put the total American investment in the fertilizer and kindred industries.”

The article discusses the sources of nitrogen, phosphoric acid, and potash, the manufacture of sulphuric acid, the phosphate mining industry, and the present status and outlook of the fertilizer industry.

Phosphate rock. E. W. PARKER (*Tradesman*, 44 (1901), No. 9, p. 81).—In an extended article on the development of the mineral resources of the Southern States the author gives some statistics of the phosphate industry. These show that while a little phosphate rock was mined in North Carolina in 1899, practically the entire product came from Florida, Tennessee, and South Carolina in the order named. The total production of these States in 1899 was 726,420 long tons, valued at \$2,804,061; 430,192 tons, valued at \$1,192,916; and 356,650 tons, valued at \$1,078,099, respectively. “South Carolina, which now ranks third, was the only State producing phosphate rock in 1880, at which time the output amounted to 190,763 long

tons, valued at \$1,001,556. Mining began in Florida in 1889, and in 1890, 45,501 long tons, valued at \$338,190, were produced. The discovery of phosphate rock in Tennessee was made in 1893, but actual mining did not begin until the following year, when 19,188 long tons were produced."

Report on the phosphate deposits of Egypt (*Geological Survey of Egypt. Cairo: National Printing Dept., 1900, pp. 27, maps 3*).—Descriptions, with analyses, are given of phosphate deposits in 3 localities, namely, in the peninsula of Sinai, lower Egypt, and Dakhla Oasis. The deposits are said to be very extensive. The analyses reported show that the proportion of tricalcium phosphate varies from 12.94 to 60.97 per cent. The phosphates are not suited to the manufacture of super-phosphates.

On the application of lime upon a sour soil before and after seeding to grass, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1899, pp. 171-173*).—A brief account is given of plat experiments at the station during 1898 and 1899, which "illustrates in the most striking manner that in seeding sour (acid) land to timothy, lime should be thoroughly worked into the soil before the seed is sown. A top-dressing of lime applied subsequently to seeding, while it may prove somewhat helpful, exerts but little benefit in connection with timothy as compared with lime harrowed into the soil."

Analyses of commercial fertilizers, H. J. WHEELER, B. L. HARTWELL, ET AL. (*Rhode Island Sta. Bul. 70, pp. 11*).—Analyses and valuations of 55 samples of fertilizers are reported.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 66, pp. 117-132*).—A previous bulletin (E. S. R., 12, p. 324) reported analyses of most of the samples of fertilizers furnished by manufacturers as required by the State law. The present bulletin contains analyses of 157 samples of fertilizers collected on the open market by agents of the station and also of manufacturers' samples received after the previous bulletin was issued. Attention is called to the fact that 70 brands of fertilizers offered for sale in the State "carried, in the case of at least one of the ingredients, a different statement on the bag from the certified statement filed with the station. . . . In about one-third of the cases the figures on the packages are but slightly lower than the certified guarantees. . . . A comparison of the results of the analyses of the samples collected by the station with the percentages guaranteed by the manufacturers shows that many of the manufacturers do not intend to do much more than make good the minimum guarantee, and it is not surprising that this results in some of the goods falling below the guarantee in one or more ingredients."

The collective exhibit of German fertilizers and chemical products, MAIZIÈRES (*L'Engrais, 15 (1900), No. 39, pp. 924-926*).—This article contains, among other data, statistics of the consumption of Stassfurt potash salts in different countries.

FIELD CROPS.

On the relation of climate to the size of grain of cereals, J. L. JENSEN (*Tidsskr. Landbr. Plantearb., 5 (1899), pp. 138-147*).—The author secured 731 samples of barley, oats, rye, and wheat through Danish consulates in foreign countries for the purpose of studying questions relating to grain rusts and their prevention. All but 26 of the samples came from 12 different countries in Europe and America and, in addition, 83 samples were obtained from Danish farmers. The average weight of 10,000 kernels was determined for each cereal from each country. The data were then averaged for the 4 cereals men-

tioned, placing the different countries in the order of decreasing grain weights, the results being as follows:

Average grain weights of cereals from different countries.

Country.	Number of sam- ples.	Weight of 10,000 kernels.	Country.	Number of sam- ples.	Weight of 10,000 kernels.
		<i>Grams.</i>			<i>Grams.</i>
Italy.....	52	418	Sweden.....	83	329
Spain.....	12	392	Germany.....	109	325
Great Britain.....	72	365	Prussia.....	88	317
Denmark.....	83	362	Norway.....	67	306
France.....	47	358	United States.....	27	285
Netherlands.....	52	354	Russia.....	18	256
Belgium.....	48	347			

The countries mentioned were placed in 6 groups, according to their climatic characteristics, Russia, with strongly marked continental climate and warm summers, forming Group I; and Italy, Spain, and France, with insular and coast climate and warm summers, forming Group VI. The different groups furnish the following average data as to grain weights of the leading cereals:

Grain weights according to climatic conditions.

Group.	Countries.	Barley.	Oats.	Rye.	Wheat.	Average.	Ratio
		<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>
I	Russia.....	333	245	178	244	250	100
II	United States.....	347	253	194	346	285	114
III	Germany, Prussia.....	399	302	231	353	321	128
IV	Denmark, Sweden, Norway.....	410	322	244	354	332	133
V	Great Britain, Netherlands, Belgium.....	440	311	266	405	355	142
VI	Italy, Spain, France.....	465	329	295	468	389	156
	Average continental climate.....	360	267	201	314
	Average insular and coast climate ..	438	321	268	409
	Data for continental climate=100 ...	122	120	133	130

The results of the investigation plainly show that the grain weights of cereals decrease in the same ratio as the continental character of the country becomes more marked and *vice versa*. The grain weight increases as the country has insular or coast climate and, in connection with such climate, it also increases with increasing temperature within the limits included by the material at hand. The different kinds of grain samples from each country were mixed and sown on experimental plats the following spring. Examinations of the grain weights of the oats and the barley harvested showed that the percentage increase in the grain weight was largest in case of the samples of Group I, viz. 12 and 20 per cent for barley and oats, respectively, and decreased almost regularly till Group VI was reached, which showed a percentage increase of 6 and 2 per cent for barley and oats, respectively. The cause of the increase in the grain weights of groups IV to VI is found in the favorable conditions of heat and rain in Denmark during the season when the crops were grown.—F. W. WOLL.

Alinit in the culture of cereals, L. MALPEAUX (*Ann. Agron.*, 26 (1900), No. 4, pp. 196-211).—The author briefly reviews the work of investigators in different countries of Europe on the use of Alinit, and gives the results of his own experiments in inoculating wheat and oats with it. Both pot and field trials were made, and the soil used varied from sterile sand to rich garden soil.

In sterile soil Alinit did not increase the yields of either grain or straw, and the use of sugar did not add to its efficiency. In field soils of average fertility the same results were obtained. In garden soils the use of Alinit resulted in increased yields, seemingly due to its presence, but the increase in yield was not as great as that obtained when nitrate of soda was used.

It is concluded that to be profitable Alinit must be used in soils rich in vegetable matter and therefore favorable to the growth of nitrifying bacteria. From the results obtained in these experiments the author believes that it will be necessary to renounce the hope of replacing nitrogenous manures by inoculation of seed with pure cultures of nitrogen-fixing bacteria.

Fertilization of grain and grass lands, A. T. NEALE (*Delaware Sta. Rpt.* 1899, pp. 24-26).—The yield of the hay crop on land fertilized in 1897 with basic slag, ground bone, and acid phosphate, respectively, and with mixtures of either basic slag or ground bone with acid phosphate is given for 1899, in addition to the data already recorded for the 2 years preceding (*E. S. R.*, 11, p. 141). The relative value of the 3 fertilizers in combinations are compared and the profits and losses for the whole 3 years' experiments discussed. Ground bone cost \$24 per ton. It was practically without effect on the grain yield of rye, but considerably increased the following crop of grass. Basic slag cost \$9 per ton. It was also negative in effect on grain, but was twice as effective as ground bone in increasing the hay yields. The profits and losses secured for the whole 3 years of the experiment are summed up by the author as follows:

"The sum total of 3 years' crops from unfertilized land is \$48.16 per acre. Fertilized land in 2 instances only equaled or exceeded this amount, viz, where the acid phosphate was used alone, from which \$52.89 represents values after fertilizer bills had been paid; and where the mixture of this phosphate with basic slag was used, this netted \$50.29.

"An investment in acid phosphate of \$1.36 per acre paid for itself the first year, and during the entire interval of 3 years returned \$4.73 profit per acre, or nearly 3 times its first cost. Of the gross return due to this phosphate, viz, \$6.09 per acre, 66 per cent must be credited to the grain and 34 per cent to the grass.

"The slag and phosphate combination returned a net profit of \$2.13 per acre. Its gross return was \$4.83, of which 70 per cent should be credited to the hay crop and 30 per cent to the grain.

"The gross return from bone and phosphate amounted to \$5.11 per acre, insufficient to meet bills for fertilizers, which amounted to \$5.80 per acre."

In the author's opinion the results obtained in this experiment point strongly to the use of acid phosphate as the most profitable fertilizing ingredient in grain and grass culture.

Comparative trial of different clover and grass mixtures for seeding. H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1899, pp. 168-170*).—A number of grass and clover mixtures were used for seeding different plats for the purpose of determining the relative yields and periods of maturity.

On the grass plats a mixture of *Bromus inermis*, meadow fescue, and orchard grass was used on one plat, orchard grass alone on another, and *Bromus inermis* and meadow fescue on a third. On the clover plats common red clover and alsike, respectively, were combined with timothy and redtop. The grass plats were ready to cut about 3 weeks before the clover plats, but the yields on the latter were more than double those obtained from the grass plats. For practical purposes the combination of clover, redtop, and timothy is believed to be the best mixture tried. On large farms the hay crop can be better cared for if mixtures are used which mature at different dates.

The Golden Vine field pea; its composition and yield per acre. J. STEWART (*Utah Sta. Bul. 69, pp. 313-328*).—The chemical composition (food value) and yield per acre of the whole plant and the leaves, stalks, and pods at different stages of growth were investigated. "Three-fourths of the plant consists of leaves when it is young and one-fourth of stalks. At maturity a little more than two-fifths are leaves, a little more than one-fifth stalks, and a little less than two-fifths pods. . . . The percentage of leaves decreases from youth to maturity; the percentage of stalk increases until the pods begin to form, and then decreases."

On June 19, when the peas were about 9 in. high, 88.3 per cent of the whole green plant was water. The greatest yield of both green and dry matter in the whole plant occurred July 10, after which no further growth of leaves or stalks took place. Two-thirds of the whole crop at this time consisted of leaves. Two weeks later, or July 24, the pods contained their greatest weight of both green and dry matter. The yield of dry material July 10 was, for the whole plant, 4,997 lbs. per acre, divided as follows: Leaves 3,347 lbs., stalks 1,391 lbs., flowers 259 lbs. When the pods were mature, July 24, the total yield of dry matter was 3,496 lbs., divided as follows: Leaves 1,699 lbs., stalks 689 lbs., pods 1,108 lbs.

The peas developed rapidly after they had become thoroughly established. Over four-fifths of the entire weight of the crop on July 10 had been produced during the 3 previous weeks. The following table shows the percentage composition of the whole plant and of different portions on the day when the yield of dry matter was greatest—July 10—and 2 weeks later, when the pods were mature:

Composition of Golden Vine field peas.

	July 10—just coming into bloom.				July 24—pods mature.			
	Whole plant.	Leaves.	Stalks.	Flowers.	Whole plant.	Leaves.	Stalks.	Pods.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Ash	11.33	12.25	9.70	8.11	10.68	14.07	9.33	6.32
Crude fiber.....	18.11	10.75	37.21	10.84	21.08	16.09	42.70	15.30
Fat	3.19	4.02	1.34	2.54	3.51	4.67	1.19	3.20
Nitrogen-free extract..	40.70	41.46	38.96	40.15	44.69	46.84	41.52	43.33
Protein	26.67	31.52	12.79	38.36	20.04	18.33	5.26	31.85
Albuminoids.....		20.95	6.69		16.02	13.15	4.06	27.87
Amids		10.57	6.10		4.02	5.18	1.20	3.98

With the above percentages and tables showing the total yield of green and dry material at different dates, the amounts of the different food constituents and ash contained in the plant at various stages of growth are worked out. Thus July 10, when the plants were just coming into bloom, the date of greatest total yield, the nitrogen-free extract constituted 2,033 lbs. of the total yield, protein 1,333 lbs., crude fiber 905 lbs., ash 556 lbs., and fat 159 lbs. These constituents were greatest for the whole plant, leaves, and stalk on this date. The leaves were especially rich in food constituents, containing "about ten-thirteenths of the protein of the plant, about thirteen-twentieths of the nitrogen-free extent, and about thirteen-sixteenths of the fat, while they contained very little more than one-third of the crude fiber."

These data suggest the early blooming period of Golden Vine field peas as the most suitable time for harvesting to secure the greatest amount of dry matter and of food ingredients.

Rice—preparation, cultivation, flooding, and harvesting, W. C. STUBBS (*Louisiana Stas. Bul.* 61, 2. ser., pp. 376-401, pls. 10).—The lands best adapted to this crop, methods of soil preparation, planting, flooding, and harvesting the crop, varieties cultivated in both the alluvial and prairie sections of Louisiana, composition of rice and its straw, etc., are popularly discussed. Some data regarding the production of rice in Louisiana, irrigation methods employed, money invested in irrigation plants, and the acreage under irrigation are included.

In 1899 Louisiana produced 107,792,000 lbs. of rice. It is estimated that about 8,000 square miles of the alluvial and prairie lands of the State could, with some expenditure of money, be brought under cultivation and irrigation where they would be valuable for rice culture. With the present yields something like 5,000,000,000 lbs. of clean rice could be raised on this land, which is about 12 times the present consumption of rice in this country. At the present time there are about 400 miles of canals constructed in the State which irrigate some 225,000 acres of rice. These canals are filled mainly by the aid of pumping plants.

Considerable data obtained by addressing letters of inquiry to rice planters are included on the management of rice plantations.

Progress of the beet-sugar industry in the United States in 1899, with a supplementary report on the cane-sugar industry of the Hawaiian Islands (*U. S. House Representatives, 56. Cong., 1. Session, Doc. 699, pp. 200, maps 4, diag. 1*).—This report is similar in character to that published in 1898 (E. S. R., 11, p. 535), and deals with the present status of the sugar-beet industry in this country and of the cane-sugar industry in the Hawaiian Islands.

Report of the special agent, C. F. Saylor (pp. 11-134).—A considerably detailed report is given of the operations of the sugar-beet factories in the different States during the season, data as regards capacity of plants, quantity of beets worked up, sugar produced, etc., being included. Sugar-beet factories are now in successful operation in California, New Mexico, Utah, Nebraska, New York, Oregon, Minnesota, Illinois, Washington, Colorado, and Michigan. The greatest activity in beet-sugar production during the year occurred in Michigan, where 8 new factories were put in operation. Some general information regarding the culture of sugar beets is reprinted from the report of 1898, and the feeding value of sugar-beet pulp for cattle and sheep is further discussed. The conditions incident to the distribution of the bounties offered by certain States for the production of beet sugar are recorded. Many reports from the directors of the experiment stations giving data in regard to the culture, sugar content, and purity coefficient of beets grown at the stations are given in the report. A considerable portion of these data have already been published in bulletins by the different stations.

In the discussion of the general conditions affecting the sugar industry of the Hawaiian Islands their locality, topography, and climate, soil, and trade conditions are set forth at length, the purpose being to show in a measure the probable future production of cane sugar and the bearing this will have on the sugar-beet industry in this country. The main factors which will control the production of sugar cane in the islands are the limited land areas suitable for the purpose and the cost of pumping irrigation water where irrigation is necessary and water can not be obtained by other means.

The production of sugar in the islands for 1900 is estimated at 310,000 tons, and the amount produced each year is increasing. Careful estimates place the limit of production for the islands at 500,000 tons. Present methods of cane culture and sugar manufacture in the islands are carried on largely by animal and steam power and are in a high state of development. It requires 18 months to produce the first crop of cane. Planters ratoon once and sometimes twice where they can produce 30 tons per acre, but a considerable acreage is produced without ratooning at all. The yield generally averages 5 tons of

sugar per acre, but sometimes runs as high as 14 tons. The cost of production varies from \$22.50 to \$44 per ton of sugar in the data given, and will average \$35 or more. The profit per ton of sugar varies from \$25 to \$35.

Conditions that will tend to increase the cost of production are the probable higher wages that will have to be paid for labor when present contracts with Chinese and Japanese laborers expire. The annexation of the islands to the United States will prevent the emigration of Chinese to the islands and prohibit the importation of contract labor from other countries.

Statistics regarding public lands in the islands, sugar factories, imports and exports, labor, and wages are given, with descriptions of all the principal sugar plantations and factories in operation in the islands.

Report of the chemist, II. W. Wiley (pp. 136-193).—In 1898, 42,110 lbs. of sugar-beet seed was distributed by the Division of Botany of this Department, nearly one-half going to 29 of the experiment stations, and the remainder to individuals and associations. In 1899, 964 samples of beets from 41 States and Territories were received, and the data secured in their analysis by the Division of Chemistry are shown in tables and summarized for 3 years. From the data at hand the adaptation of the different States for sugar production is summed up as follows: Beet sugar can be produced profitably in California, Colorado, Michigan, Nebraska, Nevada, New York, Pennsylvania, Utah, Wisconsin, and Wyoming. It can not be produced with profit in Arkansas, District of Columbia, Georgia, Kansas, Kentucky, North Carolina, Oklahoma, South Carolina, and Tennessee. It may possibly be produced at a profit in Connecticut, Delaware, Idaho, Illinois, Indiana, Iowa, Maryland, Massachusetts, Minnesota, Missouri, Montana, New Hampshire, New Jersey, New Mexico, North Dakota, Ohio, Oregon, South Dakota, Vermont, Virginia, and Washington.

The methods employed by factories in Michigan for determining the deductions to be made for tare, the analysis of beets, etc., are given in detail.

Investigation of Sumatra tobacco, A. VAN BIJLERT (*Meded. 'S. Lands Plantentuin, 1899, No. 30, pp. 156*).—The author gives an account of work done on texture and chemical composition of 15 samples of unfermented Sumatra tobacco. Since this tobacco is used exclusively for cigar wrappers, the flavor and fragrance received no attention, but the weight, elasticity, burning quality, white ash, amount of leaf surface, together with color, spotting, etc., were carefully noted.

The relation between weight and the extent of leaf surface is given, the different measurements and weights being tabulated. From this it appears that there is no constant relation between the character of the

soil and the weight and surface area of the leaves, nor is there a constant relation between surface area and weight of a square meter; and, consequently, no relation between surface area and the number of square meters of leaf surface in 1 kg. of leaves. It also appears that the texture and weight of leaves vary as much on similar soils with the same treatment as they do on different soils or with different treatment.

The results of chemical analysis are shown in 6 tables and discussed at length, and the methods of analysis employed are described.

The most common cause of failure of the crop or of unsatisfactory quality is drought. It is held that the soils on which tobacco is grown to-day have not as great power to retain moisture as they once had. Ten years ago the crop was not ruined until 40 days had passed without rain; a few years later 24 days of drought brought failure; and at present planters complain of the extremely dry weather when but 15 days have passed without rain. The decrease in the power of soils to hold water is attributed to a change in their texture and in the humus content brought about by continuous tobacco growing and frequent burning. Tobacco grown on virgin soil or on low land where the ground water is near the surface can successfully withstand a drought that will prove disastrous to plants grown on an old field. The author points out that it is more important to know the number of days of continuous drought than to know the number of inches of rain that have fallen in a given time.

Success in tobacco growing depends primarily upon the supply of fresh water. The weather and the texture of the soil are important only as they affect the water supply and the formation and movement of salts. That the size of the soil particles is of little importance is shown by the fact that tobacco differing but slightly can be raised on white clay or on coarse sand.

Good tobacco can be grown in the neighborhood of the sea if the location is sheltered from the sea breeze so that the salt particles are not carried to the land. Good tobacco can not, however, be produced on soil which contains salt, and the presence of salt-loving wild plants indicates a soil unfit for tobacco growing.

The quality of the leaf is injured when it contains large proportions of lime, chlorids, sulphates, or nitrates. Potash is desirable since it adds to the burning qualities of the leaf. Guano is a frequent source of injury because it affords such a ready supply of nitrates. This is particularly true during periods of drought, when the nitrifying bacteria are especially active and the nitrates are not washed out of the soil by the rains. During such dry periods the plants do not make a vigorous root development and consequently they reach only a small quantity of the potash which is fixed, while the mobile salts and the lime are carried up by the ascending water current and brought within reach of the plant. The nitrates are absorbed by the plant and stored in the leaf and injure the quality of the tobacco.—H. M. PIETERS.

Researches on the vegetation of some forage plants, MONVOISIN (*Ann. Agron.*, 26 (1900), No. 2, pp. 77-103).—The development of the roots and stems of vetch, crimson clover, lentils, sainfoin, alfalfa, blue melilot, Siberian melilot, burnet, English and Italian rye grass, milfoil, and other forage plants, as regards ash and nitrogen content at different periods before and after flowering, was studied. The mineral matter of the plants examined was found in greatest abundance in the roots of annuals at a period intermediate between flowering and the end of vegetation. The total nitrogenous matter was found to be greatest about the last of April and diminished from that date. The roots of legumes were richer in nitrogen than the roots of grasses. The nonalbuminoid nitrogenous material was greatest at the end of the vegetation period. The plants constantly lost in dry matter after maturity.

Results of a comparative culture experiment with French and American alfalfa, F. F. BRUJUNG, Jr. (*Organ. Ver. Ondleer. Rijks Landbouwschool* (1900), No. 154, p. 143).—An account of plat experiments on sandy soil with Poitou, Province, and American alfalfa. Plats of each were planted the middle of April, 1899, and were cut August 1, and October 19, and a third time June 11, 1900. At the last cutting the plats were very weedy and the percentage of weeds in each plat was determined. The results recorded show that the Poitou alfalfa was the best for this sandy soil, and the American the poorest.—H. M. PIETERS.

The cassava plant—its uses and possibilities, D. R. PILLSBURY (*Tradesman*, 44 (1901), No. 9, pp. 146-148).—This article discusses the history, varieties, and uses as a food and feeding stuff and for the manufacture of beverages and starch of this plant.

The races of corn, A. S. HITCHCOCK (*Amer. Gard.*, 21 (1900), No. 314, pp. 869, 870).—Dent, sweet, flint, pop, and soft corn are briefly characterized.

Chemical composition of maize and its products, H. W. WILEY (*U. S. Dept. Agr., Division of Chemistry Circ. No. 6*, pp. 13).—This is a translation into the French language by E. Gain of Bulletin No. 50 of the Division of Chemistry of this Department (E. S. R., 10, p. 624).

Flax culture experiments of the German Agricultural Society in 1899, KUHNERT (*Mitt. Deut. Landw. Gesell.*, 15 (1900), No. 5, pp. 49-52).—The results of seeding different amounts of flax on various soils as regards yield of seed and fiber are reported. The soils used were medium clay, heavy clay, clay loam, sandy loam, and clay loam containing humus. Four plats of each soil were used, and 150, 180, 210, and 240 kg. per hectare of seed sown. The largest amount of seed obtained per hectare, an average of 1,610 kg., was from the heaviest seeding. The lightest seeding, however, yielded within 4 kg. of this amount, 1,606 kg. per hectare. The greatest total amount of fiber and the greatest amount of long fiber was obtained from the plats seeded at the rate of 150 kg. per hectare. These results are at variance with those obtained in preceding years, and the test is to be continued.

Experiments on hops, 1900 (*Jour. Southeast. Agr. Col. Wye*, 1900, No. 9, pp. 5-18).—Data for cultural and fertilizer experiments at several different centers.

Experiments on the growth of wheat and maize at the Cawnpore experimental farm, India, J. W. LEATHER (*Dept. Land Records and Agr., Northwestern Provinces and Oudh, Bul. 8*, pp. 34, dgms. 2).—An account is given of growing wheat and maize for a number of years in succession on the same land with and without fertilizers, and the results obtained are compared with those secured at Rothamsted and Woburn. Cattle and sheep manure and pondrette have proven about equally valuable as a fertilizer for wheat, and wheat alternated with corn has given better results than wheat grown in continuous cultivation.

Applying manures, BERTHAULT (*Semaine Agr.*, 20 (1900), Nos. 1013, pp. 330, 331; 1015, pp. 346, 347).—The relative value of applying manures broadcast, in drills, and locally about the plant is considered for a number of farm crops.

A field experiment with Nitragin (kidney vetch), O. BURCHARD (*Landw. Wehnbl. Schleswig-Holstein*, 50 (1900), No. 30, pp. 517, 518).—The yield of kidney

vetch on uninoculated soil was at the rate of 12,750 lbs. of green fodder per hectare. When the soil was inoculated with pure cultures mixed with sand and harrowed deep into the soil the yield was at the rate of 15,286 lbs. per hectare. When the seed was inoculated before sowing the yield averaged 14,644 lbs. per hectare.

Memoranda of the Rothamsted experiments, 1900, J. H. GILBERT (*Report to the Leves Agr. Trust Committee, 1900, pp. 119, figs. 2, dgm. 5*).—This report adds the data secured in 1900 to that obtained during the preceding 56 years and summarizes the whole. This work has been previously noted (E. S. R., 11, p. 842).

HORTICULTURE.

The horticultural division, F. W. CARD and G. E. ADAMS (*Rhode Island Sta. Rpt. 1899, pp. 127-138, figs. 2*).—An outline is given of the work done during the season with orchard fruits and in the pot culture of lettuce.

An experiment has been undertaken to see if one of the typical neglected and unprofitable orchards of the State can not be regenerated and put on a paying basis by ordinary attention to spraying, manuring, and cultivation. Under this treatment the trees have taken on a new lease of life and the indications are that the orchard can be made to yield good returns in the future.

A record is being kept of the blossoming period of all fruit trees at the station. Wild Goose plums blossomed too late to be cross fertilized, and hence produced no fruit.

In experiments in crossing sweet and sour varieties of cherries for the purpose of increasing the vigor of the sweet varieties and the quality of the fruit of the sour varieties, the pollen of the sour cherries failed to fructify the sweet varieties, though the fruit developed to a considerable size and formed stones, but these contained no embryo. Better results were obtained when the sour cherries were crossed by the sweet varieties. The following crosses resulted in perfect fruit: Early Richmond by Florence, Early Richmond by Black Eagle, Montmorency by Empress Eugenia, Montmorency by Florence, and Montmorency by Black Eagle.

Some experiments were undertaken to determine whether commercial fertilizers could be profitably substituted for barnyard manure in forcing lettuce. The experiments were made in pots with light, sandy, lettuce soil obtained from Auburn and with the somewhat heavier soils of the station. Manure, sand, muck, chopped-clover hay, and moss were used with the commercial fertilizers to lighten the station soil.

The result of this one test seems to indicate that as good lettuce can be grown with chemical fertilizers as with stable manures "provided something is used to lighten the soil and give it as good physical condition as is given by the use of stable manure." The chopped-clover hay used in the experiment did not have the desired effect in lightening the soil. Rotted peat and sphagnum moss, however, seemed to be very effective for this purpose.

Radishes were grown in the pots after the lettuce was removed. The largest yields were obtained from the soils in which stable manure was used; the smallest from those in which muck and chemicals were used.

An examination of the behavior of different varieties of strawberries, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Exptl. Fruit Farm Rpt. 1900, pp. 35-82, 249-251*).—In this experiment 85 varieties of strawberries have been grown for 5 years, 13 plants of each variety having been planted every year, so that in 1899 each variety was represented by plants of 5 different ages. Plants were set 2 feet apart each way. Crops from each 13 plants were gathered separately each year, and the berries counted and weighed. Other data, such as dates of first ripening in different years, meteorological conditions, deterioration of cropping power in different varieties and in size of berry, the flavor, color, firmness, and character of varieties, etc., were secured and are in part recorded. A comparison was also made with the same varieties of berries grown in various other parts of the experimental ground as regards these same points. The various features of the experiment are discussed at length. The years 1896 and 1898 were much better strawberry years than 1897 and 1899, as shown by the larger average yields, increased size of the fruit, greater yields per plant, etc., when all the varieties and ages are considered. Nevertheless, no connection could be traced between the crops obtained and the meteorological conditions observed either during or preceding the ripening period, and these observations include data on temperature, rainfall, humidity, and surface temperature.

Both the actual and relative size of the crops obtained from plants of the same or different ages varied much in different years. For example, weights of crops from 1 and 2 year old plants in 1896 stood in the proportion of 193 to 100, respectively, while in the following year the proportion was 4 to 100. The relative weights of the berries for 1, 2, and 3 year old crops were 100 : 100 : 172 in 1897 and 32 : 100 : 77 in 1898; and there was as much variation with one variety as with another. The weight of the crops increased rapidly up to 3 years, 1, 2, and 3 year old plants standing in the proportion of 31 : 100 : 122, and there was no diminution in the crop the following 2 years. In fact, there was a further increase the fifth year to 134, but since this result depends on the observations of one season only not much stress is put upon it. While the total yield of berries increased with the age of the plant, the size of the berries decreased. If the size of the berries for the 2-year old plants is taken as 100, the proportion for the different years would be as follows: First year, 115; second, 100; third, 96; fourth, 91; fifth, 82. If the value of the crop is assumed to be proportional to the yields and the size of the berries, the value of the crop from the different plants from 1 to 5

years old will show the following ratios: 34 : 100 : 117 : 111 : 110, respectively.

As regards the ripening period the averages obtained from a consideration of the data secured with all varieties show that "the cropping season of the older plants lasts longer than that of the 1-year-old plants, . . . but the advantage does not seem with any certainty to increase with the age of the plants beyond 2 years." The 1-year plants ripened their fruit earlier 3 years out of 4 than the older plants, but in 1899 the reverse was uniformly true.

A table is given in which the 20 varieties of berries that stood first in order of merit of some one quality are arranged in 7 columns, and these data are finally condensed into a list of 11 varieties which stood highest as regards the sum total of all qualities. No variety stood first in all 7 qualities or even in 5. Three varieties appeared in 4 columns and 8 in 3 columns. The variety *La Constante* stands at the head of the list with a mark of 173, whereas by the system of valuation adopted a marking of 6 is the best attainable. It is urged by the authors that too much value must not be placed on the list of best varieties because of the great variation in behavior exhibited by different varieties when placed under slightly different conditions, as shown by the supplementary plats.

In other parts of the experimental field 4 supplementary collections of strawberries were grown. The largest collection consisted of 64 of the varieties experimented with above. The plants in the supplementary beds were set a little closer together in some instances. The results obtained in these experiments with the different varieties frequently varied widely from the results obtained with the same varieties grown in the main bed. The variation was not at all in any one direction, nor was it constant as regards any one quality or character. Leaving out exceptional cases the variation on one supplementary plat was from 22 to 177 or as 1 : 8 in 1896; in 1898 the variation on this same plat was from 5 to 184 or as 1 : 37. A similar lack of consistency in the behavior of the varieties was observable during each year of the experiment on each supplementary plat and with all ages of plants.

"Without impugning our ground or manure there would seem to be ample explanation for the variations noticed when dealing with a short-lived, low-growing, and somewhat delicate plant. The crop must depend largely, if not chiefly, on the progress of events during the blossoming period, a slight difference in moisture of the soil, a slight depression in the ground, an almost imperceptible shelter from radiation, or a screening from ventilation, an accidental breath of wind, or a day earlier or later in the expansion of the flowers, may make all the difference whether the blossoms were affected by a night frost or not.

"Although these results may be regarded as unsatisfactory from the point of view of a mere 'testing of varieties,' they will have served their purpose well if they have done nothing more than prove the futility of experiments directed to this object only.

"Without implying that such a 'testing' may not have its uses in some cases, we

do not hesitate to say that a large proportion of the energy of many horticultural stations is entirely thrown away in making large collections of different varieties with the sole object of recording, often in a very slipshod and unscientific manner, their behavior at the station in question. Such work, indeed, does not deserve the name of experimental work, and even when conducted on rigorous quantitative principles, it is not likely to yield results of greater value, from the 'testing' point of view, than have our results with strawberries, nor to lead to a better knowledge of the respective merits of the varieties than might be obtained either from general repute or from an experienced nurseryman."

Experiments on different methods of treatment applied to apple trees, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900, pp. 106-209, 252-257, pls. 14, figs. 2*).—The larger part of the experimental work here reported was conducted with dwarf trees of Bramley Seedling, Cox Orange Pippin, and Potts Seedling. Each trial row usually contained 18 trees, 6 trees of each variety. Some of the experiments were repeated with Stirling Castle and others with standard trees of Bramley Cox and Lane Prince Albert. All the trees were planted in 1894-95 when the dwarfs were 3 and the standards 4 years old.

The problems investigated consisted of modifications in some one respect of the normal treatment adopted for a set of trees, and involved studies in pruning, root treatment, manuring, and planting. The normal treatment consisted in planting the trees in trenched ground and subsequently keeping the surface clean, cutting back after planting, pruning moderately in autumn, shortening growths when it appeared necessary in summer, and fertilizing with mixed minerals in autumn with a dressing of nitrate of soda in February. The results obtained were measured by (1) weighings of a certain number of air-dry leaves from the trees; and (2) measurements made in 1898 of the height, spread, and girth of the stem of the trees. Two crops of fruit were also obtained in a few instances, and in 1 or 2 cases trees were lifted and weighed. The data secured on the different phases of the experiment are recorded in considerable detail and discussed at length.

When trees were not cut back at planting nor subsequently pruned they were straggling in form and there was a general loss in vigor of growth. Nevertheless, the amount of fruit borne by such trees was in excess of the average. When the trees were cut back at planting and not subsequently pruned they assumed the general straggling form noted above but suffered no loss in vigor of growth. The experiments were slightly in favor of immediate cutting back on setting out rather than waiting until a year later. Summer pinching and summer pruning produced no noticeable results with the young trees under investigation.

Root pruning trees has resulted in checking both vigor and growth. Trees root-pruned every year were in 1898 but little more than half as large as normal trees and those pruned every other year only about

$\frac{2}{3}$ as large. "The crops borne by these trees, however, were heavy in proportion to their size." Trees carefully lifted every year and replanted at once suffered no injury thereby, but when left 3 days before planting, in imitation of commercial nursery methods, material injury resulted, amounting 4 years after the transplanting to a loss of 28 per cent in size.

The effect of growing grass about trees was most striking.

"The grass-grown trees are, after 5 years, scarcely bigger than when planted, and the actual increase in weight which they show during this time is about 18 times smaller than in the case of similar trees in tilled ground. The effect of weeds has been distinctly less than that of grass, and that of careless planting, combined with weeds and total neglect, is scarcely greater. The grassed or weed-grown area, in the majority of cases extended to about 6 ft. beyond the stems of the trees, but in the case of 2 of the varieties of standards the extent was only 3 ft., and in these instances recovery began in 1897 and now appears to be complete, so far as the vigor of the trees are concerned, although they have not made up for the loss in growth experienced before 1897. In the case of the other trees, where the ground is more efficiently grassed over, there seems to be some signs that recovery is now beginning. With those trees which have been recovering since 1897 the majority of their roots are still within the grassed area, and it seems impossible, therefore, to attribute the effects of the grass to a competition of food between the roots of the grass and those of the tree. We believe one of the main causes of the effects to be due to the large increase in the evaporation from the soil which is known to be produced by grass, the trees being thereby made to suffer from drought, with consequent deprivation of other nourishment as well; but we have reason to consider that the grass acts, also, by preventing the access of air to the roots of the trees. Further experiments have been undertaken to elucidate this action more fully."

Carelessly planted and neglected trees largely recovered when culture and attention were resumed after the first year. In these experiments carelessly planted trees resulted in an increase in growth of wood and in total weight of the tree—a surprising result which is being further studied. Mulching the ground with clean straw, hardening by rolling, or repeated digging of the soil instead of hoeing produced no appreciable results.

The effect of planting trees in hills with the ground worked from 2 to 3 ft. deep, of planting in soil mixed with flints, gravel, chalk, peat, or compost, and of planting trees too high and too low were studied. Decided results were secured only when the method employed favored an increased moisture supply to the roots—*i. e.*, with peat and compost. Both the leaf size and wood formation were increased by the use of these materials, due not so much, it is thought, to their manurial value as to their increasing the porosity and moisture of the soil. Each of the months of November, January, and March has proved equally favorably for setting out trees.

In certain experiments the blossoms were removed, resulting in a small excess in the growth and leaf weight.

"With Stirling Castle, the normal trees of which have borne much more fully than those of the other variety, the excess was much larger, amounting to 30 to 40 per cent. These trees were allowed to fruit in 1899, and immediately the excess in the size of the leaf disappeared. The crop of these trees in this one year, although it was an unfavorable year for fruit, was greater than those of the other trees throughout the 4 seasons during which the latter had been bearing."

Pecan culture, H. H. HUME (*Florida Sta. Bul.* 54, pp. 185-211, pls. 3, figs. 9).—The botany, methods of propagation and culture, varieties, and the adaptation of pecans to Florida conditions are considered.

A large portion of northern Florida is believed by the author to be especially adapted to the profitable growth of pecans. The nut does not appear to be exacting in soil requirements. Trees in Florida are found growing on soils ranging from a black hummock to the less fertile high pine lands. The opinions of writers vary as to the best soil.

Directions for growing trees from seed planted in the nursery are given. The seed bed should be prepared as for vegetables and the nuts planted on their sides 3 in. apart, in rows $2\frac{1}{2}$ ft. apart, and covered 3 in. deep. They should be planted soon after they are ripe and cultivation and fertilization given the same as with other young trees.

Varieties do not come true from seed. Grafting and budding are therefore resorted to in propagating desirable sorts. Annular and veneer shield budding or cleft and whip grafting are most common. Various other species of *Hicoria* have been used for stocks, but the pecan is considered most satisfactory.

A successful method of propagation recommended by a pecan grower is to plant common pecans and a big paper-shell variety close beside each other, and when 2 years old to use the paper-shell as scion and the common pecan as stock. The scion should contain 3 buds. It is taken before growth starts in the spring and kept in moist sand. Later, when the stock has plenty of sap and is putting out leaves, the ground is cleared away from the crown and an oblique cut $\frac{1}{2}$ to 1 in. in length, made from the crown upward. A similar cut is made on the scion. The graft is held in place by a mixture of clay and gray moss, well mixed and kneaded, and earth heaped over the stock. The pecan is considered difficult to work, which fact largely accounts for the high price of pecan nursery stock.

The orchard where the trees are to be set should have been in some cultivated farm or garden crop. Forty feet is believed to be sufficient distance apart for trees in Florida. If the triangular method of planting is adopted, 40 trees can be grown on an acre. Planting between the latter part of November and first of March is recommended. The trees may be set in the permanent orchard when 2 years old. If budded or grafted they will be 3 years old. A small amount of fertilizer, thoroughly incorporated with the soil about the newly set tree, is desirable. Clean cultivation may be given from March to July,

followed by a cover crop of beggar weed, cowpeas, or velvet beans; or crops of cotton, velvet beans, melons, etc., may be grown between the rows, the area devoted to these crops being more and more restricted as the trees develop.

Pecan trees have a large tap root. When transplanting, this should be cut 15 or 18 in. from the crown or back to solid wood and all injured roots removed. Root pruning trees in the nursery row is recommended. Examples of successful orchards grown from tap-root pruned trees are also noted. Pruning the tops of 1 and 2 year old trees at time of setting is not considered advisable as it tends to the development of shoots. Older trees when transplanted will require some top pruning. In general, the pruning necessary for a pecan tree is confined largely to forming the head. This should be started 3 or 4 ft. from the ground, and the strong upright center limbs cut back to induce growth of the lateral branches and give the tree a rounded form.

Some notes on the production of new varieties by crossing are given, and 18 varieties grown either in Florida or Georgia are described. The points considered desirable in estimating the value of the pecan are quality and flavor, plumpness of kernel, ease with which the kernel separates, size, and thickness of the shell. A thin-shell variety, other factors being equal, is most desirable; Stuart, Van Deman Centennial, and Frotscher are considered standard varieties. A list of nurserymen handling pecan stock is added.

Artificial pollination of carnations, AMELUNG (*Gartenflora*, 49 (1900), No. 17, pp. 458-464, figs. 5).—An account is given of cross pollinating *Dianthus chinensis* with the pollen of *D. caryophyllus* for the purpose of combining the vigorous growing habit and strong stems of the first with the rich color and odor of the latter. Incidentally pollen from *D. barbatus* and *D. plumarius* was also used to fertilize the Chinese carnation. The pollen of *D. barbatus* was effective, and 70 good seeds were obtained; but that of *D. plumarius* exerted no influence whatever. Some 100 seeds were obtained when *D. chinensis* was pollinated by *D. caryophyllus*. These were sown. None of the resulting carnations were alike in type, form, or leaf formation. Out of 60 blossoms only 3 were well filled. Ten of the more promising plants were set in pots, pollinated with *D. caryophyllus*, and the seed harvested in the fall. This seed, when sown the following spring, produced plants which blossomed at intervals between June 1 and September 30. Selected plants were again pollinated with *D. caryophyllus* and the operation repeated 3 times. The result of the experiment at the end of 6 years is a plant which blossoms earlier than *D. caryophyllus* and has a stronger stem. It is believed that after a few years this strain can be so fixed as to come true to seed. The experiment is further believed to show that it requires at least 10 years before satisfactory results can be obtained in cross pollinating carnations.

Gardener's assistant; a practical and scientific exposition of the art of gardening in all its branches, R. THOMPSON (*London: Gresham Pub. Co., 1900, rev. ed., Vol. I, pp. 208, pls. 3, figs 269*).

Amateur's practical garden book; containing the simplest directions for the growing of the commonest things about the house and garden, C. E. HUNN and L. H. BAILEY (*New York: Macmillan Co., Gardencraft, ser. 1900, pp. 250, figs. 169*).—The topics treated are arranged alphabetically. The more common fruits, nuts, vegetables, flowers, herbs, horticultural operations and tools, insects and diseases, etc., are considered in an elementary way.

Vegetable growing in southern Arizona, A. J. McCLATCHIE (*Arizona Sta. Bul. 35, pp. 114-143, figs. 5*).—Cultural directions based on the results of station experience are given for growing all the more common garden vegetables. The region in southern Arizona where the station is located is essentially a desert one, with hot days, cool nights, and rapid changes from winter to summer. Irrigation is essential. The kind of vegetable to be planted each month of the year is specifically noted and directions given for preparation of the soil, cultivation, irrigating, etc. The necessity for planting only good seed is pointed out.

Vegetables out of season in every garden, E. K. TOOGOOD (*Southampton: Toogood & Sons, 1899, pp. 103, figs. 73*).—Notes on forcing structures and appliances and directions for forcing a large number of vegetables and small fruits, with data as to time of sowing and date of maturing.

The formation of fruit buds, G. H. POWELL (*Delaware Sta. Rpt. 1899, pp. 150-153*).—A study is being made of this subject in the laboratory and field, but results thus far obtained are reserved for a future report. Inconclusive data obtained in thinning experiments with Burbank and Poole Pride plums are included. Thinning slightly increased the size of the fruit but reduced the quantity and likewise the profits per tree. The value of thinning in the case of the Burbank it is thought must be found in the subsequent behavior of the tree. With Poole Pride the main advantage seemed to be the excellent condition in which the trees were left for future crops. Branches of unthinned trees were bent to the ground with the fruit and so broken that a renewal of the tops will be necessary before further crops can be grown.

Fruit culture in Queensland, A. H. BENSON (*Queensland Agr. Jour., 7 (1900), No. 5, pp. 432-438, pls. 11*).—A short account of some varieties of citrus fruits of approved merit now fruiting in the colony, with general notes on seedlings.

The chemical composition of Finnish cranberries, F. STOLLE (*Ztschr. Deut. Zuckerind., 50 (1900), No. 533, pp. 609, 610; abs. in Jour. Soc. Chem. Ind., 19 (1900), No. 9, p. 841*).—The details of the chemical method employed in isolating the sugar contained in the fruit are reported. The sugar in the cranberry was found to be pure invert sugar, and the acid, glyoxylic acid.

Catalogue of fruit trees under test at the experimental farm at Agassiz, British Columbia, W. SAUNDERS and T. A. SHARPE (*Canada Cent. Expt. Farm Bul. 3, 2. ser., pp. 71*).—Alphabetical lists of the apples, crab apples, pears, plums, cherries, peaches, apricots, nectarines, quinces, medlar trees, and mulberries growing at the station with notes and a select list of the varieties suitable for cultivation in British Columbia.

Root system in the orange orchard as affected by irrigation, cultivation, and fertilization, J. H. REED (*Pacific Rural Press, 61 (1901), No. 1, pp. 4, 5*).—Paper read by the author before the University Farmers' Club Institute at Riverside, Cal.

Messina v. California lemons, J. S. VAN EPPS (*Pacific Fruit World, 10 (1901), No. 15, p. 3*).—The total weight and the weight and percentage of the peel, pulp, soluble solids, and free and combined acids of a box of California and a box of Messina lemons each containing 300 lemons are given. The California lemons contained about one-third more acid than the Messina.

The California Smyrna fig on a commercial basis, G. C. ROEDING (*California*

Fruit Grower, 25 (1900), No. 656, pp. 4-6).—Paper on this subject discussing in detail Smyrna and Adriatic classes of figs, caprification, gathering and curing, etc.

Phylloxera resistant vines for California, F. T. BIOLETTI (*Pacific Rural Press*, 60 (1900), No. 25, pp. 388, 389).—Paper read by the author at the California Fruit Growers' convention.

Preservation of grape posts, SCHELLENBERG (*Jahresber. Vers. Stat. u. Schule, Wädenswil*, 1897-98, pp. 43, 44).—Posts saturated with solutions of copper sulphate, carbolic acid preparations, or creosote, respectively, resisted rot much longer than posts not so treated.

Growing flowers for perfume, O. B. SALISBURY (*Amer. Gard.*, 21 (1900), No. 313, pp. 847, 848, figs. 3).—An account, with some statistics, of the perfume industry of the city of Grasse in southeastern France.

Culture of flowers from seeds and bulbs, E. K. TOOGOOD (*Southampton: Toogood & Sons*, 1900, pp. 190, fig. 54).—Simple directions for the culture of hardy flowers.

Live covers for country homes, B. D. HALSTED (*New Jersey Stat. Bul.* 144, pp. 39, pls. 15, figs. 13).—A popular treatise on all the more common hardy climbing vines used in this country for ornamental purposes and shade for houses and other buildings. The ivies, grapes, Wistarias, Ampelopsis, trumpet creeper, Clematis, honey-suckle, climbing roses, pipe vines, matrimony vine, *Akebia quinata*, moonseed, climbing bittersweet, Actinidia, hop, and Madeira vine, and Cobea annuals are given most attention. The success or failure with many of these at other stations in different parts of the country is noted. Directions for setting vines are given, with notes on their care, diseases, etc., and a brief presentation of the objections from a sanitary standpoint sometimes urged against vines on houses.

Culture of Erica wilmorei and of similar species, H. DAUTHENAY (*Rev. Hort.*, 72 (1900), No. 23, pp. 663, 664).—Details regarding propagation, care, and diseases.

Auricula (Primula auricula), J. DOUGLAS (*Garden*, 58 (1900), Nos. 1515, pp. 399-401; 1516, pp. 411, 412).—Paper on the classes of auriculas, general culture, propagation by seed, repotting, insect pests, and best varieties, with notes on alpine auriculas.

FORESTRY.

A short account of the Big Trees of California (*U. S. Dept. Agr., Division of Forestry Bul.* 28, pp. 30, pls. 15, maps 2).—This is a reprint of a report on the Big Trees of California which was issued as a Senate document. It contains a statement relative to the discovery of the groves and their distribution throughout California. The Big Tree is found only in small groves scattered along the west slope of the Sierra Nevada Mountains, from the North Fork of the American River to the head of Deer Creek, a distance of 260 miles. But 10 main groups are known, and the total number of large trees in these groups are but a few thousand, while the specimens which are remarkable for their size do not exceed 500. The different groves are described in detail, and notes are given on their age, geological history, etc. The Big Tree reproduces itself but slowly and with much uncertainty. In some groves a number of seedlings of varying size are found, while in others young trees are almost wholly wanting. A botanical description of the Big Tree is given, together with notes on its nomenclature, in which it is stated that the proper botanical

name of the tree should be *Sequoia washingtoniana*, instead of *S. gigantea*.

The Big Trees of California, W. R. DUDLEY (*Forester*, 6 (1900), No. 9, pp. 206-210, fig. 1).—The author gives a concise statement of the facts observed in an investigation of the Big-Tree regions of California, in which he visited various groves, took the measurements of the trees, studied their habitat as closely as possible, and incidentally secured information relative to their ownership. It is said there are 33 distinct groves of *Sequoia gigantea*, 8 of them north and 25 south of Kings River, California.

The result of lumbering these trees is mentioned, and the milling capacity of the various mills situated in the vicinity of the different groves is shown. The agitation that is going on for the acquirement of these groves by the Government, and their future protection, has both a sentimental and an economic value. South of the Kings River these trees are said to be an important factor in stream protection, and as such their preservation becomes an important forestry question.

Tree planting in Oklahoma, W. L. HALL (*Forester*, 6 (1900), No. 6, pp. 130, 131).—The forest conditions of Oklahoma are briefly described, together with the soils and distribution of streams. Under proper management it is said that many thousand acres of land at present almost worthless could be made to produce valuable timber at slight expense. In this region planting white elm, green ash, mulberry, catalpa, locust, Russian mulberry, hackberry, black walnut, and black cherry may be usually relied upon to be successful. Plantings of these trees should be on the lower slopes and in the valleys, but if upland planting is attempted it is stated that it should be carried on in a limited way with such trees as black locust, Russian mulberry, white elm, and hackberry.

When increase in thickness begins in trees, G. T. HASTINGS (*Science*, n. ser., 12 (1900), No. 303, pp. 585, 586).—A brief summary is given of observations made upon the beginning of increase in thickness in a number of trees. It was found that in the broad-leaved species examined no increase of thickness occurred until the buds had opened and the first leaves expanded. The first formation of new wood was in the neighborhood of the terminal bud, and was not continuous around the stem. The growth progresses gradually from the 1-year-old twigs to those 2 and 3 years old, and when the new wood begins to be formed on the 5 or 6 year old twigs, the process becomes very rapid, occurring over the entire tree. Growth usually begins and extends more rapidly on the upper and more exposed limbs, sometimes a week before any sign of growth being observed on the lower ones.

In the pines the increase in thickness began on the 2 and 3 year old twigs before it was noticed in 1-year-old twigs, or before the buds had

opened. By the time the buds were well opened growth had extended from the terminal shoot down the trunk and was just beginning on the lower branches. This exceptional behavior is attributed to the fact that the leaves, as in the case of the pine, remain on the twigs for 2 or 3 years. In the case of hemlock, which retains its leaves for 6 or 7 years, the growth at the end of May was greatest on the 6-year-old twigs, and decreased up to the 1-year-old twigs, where it was very slight. In the case of the bald cypress (*Taxodium distichum*) the conditions were quite similar to those observed for the broad-leaved, deciduous trees.

Damage to timber by acid fumes, H. S. GRAVES (*Forester*, 6 (1900), No. 6, pp. 135, 136).—An example of injury to timber by acid fumes is reported by the author as occurring at Ducktown, Tenn., where there are extensive copper mines. The crude ore is roasted in order to drive off a portion of the sulphur. The fumes, containing a large amount of sulphurous acid, are carried to a considerable distance, all grass being destroyed for about one-third of a mile, and at a distance of one-half mile certain trees are only able to maintain a sickly existence. It was found that the white pine was among the most susceptible. Trees of this variety have been killed at a distance of 7 miles from the roasting sheds.

A provisional list of trees, in the order of their relative degree of sensitiveness, is given. The list, beginning with the most sensitive, is white pine, hemlock, river birch, mulberry, white oak, chestnut oak, chestnut, black oak, red oak, ash, willow, beech, poplar, blue beech, bellwood, locust, honey locust, red maple, Virginia scrub pine, black gum, sourwood, and dogwood. The last 3 trees in the list are said to be very hardy and are found growing in excellent condition within half a mile of the works.

The forests, L. BOPPE and A. JOLYET (*Les Forêts*. Paris: Baillière & Son, 1901, pp. XI + 488, figs. 94).—This book is largely based upon lectures delivered by the first author at the National Forestry School at Nancy. In the first chapters the tree as an individual is considered, followed with descriptions of all the more important species of forest trees. The forest, its soil, climatic and reciprocal relationships are discussed; after which especial attention is given to forest protection and reforestation. In the chapters on exploitation and protection especial attention is given to the injuries to forests by man, in which fires and pasturage play an important part. Many valuable suggestions are given relating to artificial reforestation, the value of different species for different surroundings and uses being discussed. Directions are given for the preparation and management of forest nurseries and forest planting. Plants suited to the different conditions are presented, attention being paid to reforestation of nonagricultural lands, mountains, and the fixation of sand dunes.

The forests of Canada, DE SEBILLE (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 6, pp. 451-465).—The forests of Canada are described at some length, the different regions being taken up in more or less detail. The coniferous species occurring in these forests are mentioned and their distribution briefly outlined. Thirty-one species of conifers are found in the region indicated.

Forest problems in Michigan, C. W. GARFIELD (*Forester*, 6 (1900), No. 11, pp. 255-258).—In a paper read before the American Forestry Association, June 26, the author reviews the preliminary movements which led up to the establishment of a State forestry commission in Michigan. The text of the law, which provides for a permanent forestry commission and defines its powers and duties, is quoted. The organization of the forestry commission is given and a brief account of the efforts on the part of this commission to enforce the law and create a public sentiment favorable to it.

Adirondack forestry problems, B. E. FERNOW (*Forester*, 6 (1900), No. 10, pp. 229-234).—The acquirement of forestry lands by the State of New York is briefly reviewed, together with the legislation which has made it possible to acquire and control these forests. The main problems remaining for solution are silvicultural ones, and these will be concerned with the treatment of virgin land, culled lands, slashes or burns, and swamps.

The legislative outlook for forestry in Wisconsin, E. BRUNKEN (*Forester*, 6 (1900), No. 11, pp. 259-262).—The forestry conditions of Wisconsin are briefly outlined and statements given relative to the prospect for legislation to correct some of the more prominent evils.

The forests of East and West Prussia (*Ztschr. Forst. u. Jagdw.*, 32 (1900), No. 7, pp. 381-406).—The extent and distribution of the forests are described.

A classification of standing timber, C. BROILLIARD (*Rev. Eaux et Forêts*, 3. ser., 4 (1900), No. 5, pp. 140-149).—Different schemes of classification of standing timber are given which are varied to suit different species of trees.

Comparison of the strength of Ceylon timbers with that of European timbers, W. C. UNWIN (*Indian Forester*, 26 (1900), No. 10, pp. 521-523).—The weight per cubic foot, crushing strength, "shearing" strength, etc., are given of 22 varieties of Ceylon timbers, comparisons being made with the same factors for oak, elm, ash, and red pine.

Second growth pine vs. agriculture, W. M. HAYS (*Forester*, 6 (1900), No. 9, pp. 214-216).—Attention is called to the low value of some of the sandy pine lands in Minnesota and elsewhere after they have been denuded of timber. Such lands are quickly exhausted when cultivated, and their greatest economic value can probably be secured by maintaining them permanently under forest conditions.

The natural spreading of timber areas, C. E. BESSEY (*Forester*, 6 (1900), No. 10, pp. 240-243).—The natural spreading of pine forests and deciduous trees in the prairie regions is shown, and causes sought. The principal cause of this spread is attributed to the fact of stopping prairie fires and of adjacent tillage.

Cutting, burning, and fire protection, H. B. AYRES (*Forester*, 6 (1900), No. 11, pp. 266, 267).—A brief review is given of some of the problems relating to cutting, burning, and fire protection of forests. It is stated that investigations made by the U. S. Geological Survey show that in 14 townships during 1899 more than 800,000,000 ft. of white and Norway pine was destroyed by fire. The necessity for systems of management which will prevent such wholesale loss is shown.

Some important foreign trees for use in reforestation, F. HENRY (*Sta. Agron. Nancy, Bul. 3*, 1900, pp. 26-39).—A brief review of the forest conditions existing in France and elsewhere is given, in which the necessity for forest conservation is shown. Notes are given on the value of the black locust, white pine, and Douglas fir for forest planting in the east of France. The results of a number of experiments with these trees made in different parts of Europe are given, in which the author concludes that these trees are all available for reforestation experiments in France.

Profitable reforestation, E. HENRY (*Rev. Eaux et Forêts*, 3. ser., 4 (1900), No. 11, pp. 321-329).—An account is given of operations in reforestation. Oaks were used and the value at the end of 34 years is said to represent 6 per cent annually on the investment.

Notes on successful reforestation, E. HENRY (*Sta. Agron. Nancy, Bul. 2, 1900, pp. 31-41*).—An account is given of the successful reforestation of 2 tracts of land in eastern France, in which the Austrian pine (*Pinus laricio*) was the principal species. The seed of this, and white pine, larch, and spruce were sown in oats, the entire expense of preparation of the land and sowing the tree seed being nearly borne by the yield of oats. At the end of 34 years the value of the forests in which the Austrian pine predominated was estimated, and the statement is made that it is equal to a 6 per cent compound interest on the capital invested.

SEEDS—WEEDS.

Crimson clover seed, A. J. PIETERS (*U. S. Dept. Agr., Division of Botany Circ. 18, rev., pp. 7, figs. 3*).—In a previous edition of this circular (E. S. R., 11, pp. 748) a description was given of the crimson clover seed and methods for its inspection. The results of a year's experience have justified the fear expressed that unless care was taken to test the germination of crimson clover seed, much poor seed would be planted and disappointment follow. During the past season more than 100 samples of crimson clover seed were sent to the Seed Laboratory for examination. Their germination varied from 0 to 99.75 per cent. The purity in most cases was good, though one sample sold as crimson clover proved to be common red clover, while another lot of seed, imported as crimson clover, was yellow trefoil. A detailed report is given upon a number of analyses made, in which comparisons are drawn between the market price of the seed and the actual value of the good seed in the sample. The statement is made that as a general principle seed should be used that is grown in the neighborhood where it is to be planted. As between imported and American-grown seed, the latter is to be preferred. However, imported seed of good vitality will generally give satisfaction in the region south of the Ohio River.

The germination of seeds from different sized fruits and from cells containing different numbers of seeds, DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900, pp. 210-217*).—In the previous report (E. S. R., 9, p. 757) the germinative power of seeds of crab apples taken from large and small fruits was reported upon. The results obtained at that time seemed to be in favor of the seeds from smaller fruits. In the present report details of experiments are given with crab apples, apples, and pears, the results of which are summarized. The general conclusion reached is that neither the size of the fruit nor the number of seeds per fruit has any certain or appreciable effect on the germinative power of the seed and probably not on the vigor of the seedlings.

Investigations on germination, L. MAQUENNE (*Ann. Agron., 26 (1900), No. 7, pp. 321-322*).—The author states that the 2 conditions which are perhaps most important in the germination of seed are the

vitality of the embryo and the amount of humidity sufficient to secure the dissolution and transportation of the reserve material in the seed, and in this contribution he makes a preliminary report on the relation between these 2 factors. The amount of moisture normally in seeds and the amount present as shown by evaporation in vacuum of a number of seeds is given, and the transformation of the reserve materials in rye, peas, and white lupines is shown.

In conclusion the author states that all his observations tend to show the preponderating rôle of diastases in the preservation and development of seeds. Those causes which retard the alteration of diastases also maintain the germinative power, and it is believed possible to indefinitely prolong the vitality of seeds by placing them under conditions in which the diastases are rendered absolutely inactive. One of the most important factors in this is the presence of moisture, all traces of which must be removed for the prolonged preservation of seed.

The effect of calcium hydrate upon germination, R. WINDISCH (*Landw. Vers. Stat.*, 54 (1900), No. 3-4, pp. 283-309).—The effect of soaking seed of various kinds in water containing from 0.1724 to 5 per cent of calcium hydrate, as shown in their germination, is reported. The seeds experimented with were wheat, barley, rye, oats, maize, rape, flax, blue and white lupines, chickpea, fodder vetch, soy beans, and horse beans. Equal lots of seed were soaked for the same time in distilled water and the germination of the 2 lots compared. The results, which are tabulated, show that wheat was uninjured by any of the treatments and the other cereals not to any appreciable extent. In some cases the germination of the seed soaked in the lime solutions was retarded and with some seeds the total germinations were considerably reduced. This seemed to be especially true with the lupines, hemp, fodder vetch, horse beans, and soy beans.

Charlock spraying, T. H. MIDDLETON (*Univ. Col. Wales, Aberystwyth, Agr. Dept., Ann. Rpt. Field Expts. 1899*, pp. 43, 44; *Ed. Agr. [London], Rpt. Agr. Education and Research, 1899-1900*, pp. 89, 90).—An account is given of spraying experiments for the destruction of charlock in a field of black Tartarian oats. Copper sulphate solutions in 1.5 and 2.25 per cent solutions were employed at the rate of from 38 to 70 gal. per acre. A few days following the spraying, the oats had a brown tint and seemed to have suffered especially from the 2.25 solution. A fortnight later the unsprayed plats were a mass of yellow bloom, but on the sprayed portion but few weeds were to be found and the oats, instead of having been injured, appeared to have been distinctly benefited by the treatment. From the success which attended this experiment the author feels warranted in recommending such treatment for the destruction of charlock and gives directions for its proper application.

List of seeds of hardy herbaceous plants and of trees and shrubs (*Roy. Gard. Kew, Bul. Misc. Inform., 1901, App. I, pp. 40*).

A new seed-sorting apparatus, G. MARTINET (*Ann. Agr. Suisse, 1 (1900), No. 2, pp. 56-59, fig. 1*).—In this apparatus seeds are allowed to drop through a funnel which is curved at its lower extremity in a horizontal direction. The falling seeds acquire a certain momentum and are projected at different distances, according to their size and weight, into partitioned receptacles. The lighter seeds drop into the first receptacle while the heavier seeds are thrown farthest and intermediate grades fall between. A blast of air directed against the seeds as they leave the funnel aids in the separation.

Some results are recorded which show the germinating power of seed collected in the different receptacles.

Rice weeds in Louisiana, W. R. DODSON (*Louisiana Stat. Bul. 61, 2. ser., pp., 402-437, figs. 17*).—An account is given of the more important weeds occurring in the rice fields of Louisiana, and the methods of their distribution are discussed at considerable length. Various means of destruction are suggested; among them, burning, late plowing, flooding, hand weeding, etc. Among the weeds the most troublesome is that known as red rice, which is a variety of the cultivated rice. Among the other weeds described are the large indigo (*Sesban* or *Sesbania macrocarpa*), the curly indigo (*Eschynomene virginica*), tadpole grass (*Rhynchospora corniculata*), bull grass (*Panicum agrostidiforme*), etc.

DISEASES OF PLANTS.

Upon the after effect of sulphur when applied to soils for the purpose of preventing potato scab, H. J. WHEELER, B. L. HARTWELL, and N. L. C. MOORE (*Rhode Island Sta. Rpt. 1899, pp. 163-167*).—In a previous bulletin of this station (E. S. R., 8, p. 797) the effect of sulphur applied at the rate of 600 lbs. per acre in the prevention of potato scab was described. In 1897 similar experiments were continued in which sulphur at the rate of 300 lbs. per acre was used, the seed tubers being rolled in sulphur and the sulphur not adhering to the tubers being dusted over them before covering in the hills. As a result of this treatment the number of scabby tubers was reduced about 9 per cent. An injurious action of sulphur upon the plants was noticed where no lime had been applied to the soil. The germicidal action of sulphur is explained by the acid liberated by the oxidation of the sulphur. On neutral or slightly alkaline soil a more marked influence as a preventive of scab would be expected.

In 1898 experiments were conducted to ascertain the after effect of applications of sulphur under various soil conditions. These experiments were conducted in galvanized-iron pots, the soil having been taken from pots which had been used the 2 previous years in experiments on potato scab. Each pot received a fertilizer of nitrate of soda, acid phosphate, muriate of potash, and high-grade sulphate of potash. Different pots received lime, wood ashes, or some form of calcium. Comparisons were made with and without sulphur. The experiments were conducted with oats and millet. The results, which

show the weights of air dry plants in the different pots, are tabulated, in which it appears that "sulphur employed in considerable quantities upon soils which are acid or which contain but a limited excess of basic ingredients is capable of causing much subsequent injury to crops, the extent of the same being greatest upon acid or neutral soils." It is further stated that the application of sulphur to soils for the prevention of potato scab regardless of the character of the soil is liable to occasionally cause much injury. The authors state that sulphate of ammonia, which has a high manurial value, gives promise of being more satisfactory and economical than flowers of sulphur as a means of lessening the tendency to scab in contaminated soils which are favorable to the growth of the fungus.

Experiments in the prevention of tomato blights, G. H. POWELL (*Delaware Sta. Rpt. 1899, pp. 153-156*).—Reports are given of experiments in spraying tomato plants in 1898-99 with Bordeaux mixture for the prevention of tomato blights. In 1898 various plats were sprayed at different times and with different numbers of applications. The results obtained were of a decidedly conflicting nature, some of the check plats yielding more than some of the sprayed ones. The results obtained indicated that Bordeaux mixture did not check the progress of the disease, although it was visible upon the foliage throughout the season.

In 1899 the experiments were repeated. One lot of 100 plants was covered with Bordeaux mixture from the time of their appearance above ground until the ripening of the first fruits; a similar lot was kept thoroughly sprayed from the time the plants were set in the field to the ripening of the first fruits; a third lot was sprayed from the time of setting first fruits to their ripening, and a fourth lot was retained as a check. Records were kept of the number, weight, and diseased character of all the fruits, the results of which are shown in tabular form. The plants sprayed from the time of their appearance in the seed bed gained at the rate of 2.45 tons per acre; those sprayed from the time of setting in the field, 1.24 tons; while those sprayed from the time of the setting of first fruits until their ripening gained 2.25 tons per acre. The tomato blight appeared on none of the plants until late in the summer, after which all the plants seemed to be affected alike, the foliage dropping from the sprayed as well as the check plants.

The value of Bordeaux mixture in these experiments seems to be shown in the increased vigor of the plants, having stimulated them to a more rapid growth. It was of particular merit in keeping down the attacks of flea-beetles, and spraying the seed bed is thought advisable by the author, especially if it should be on land previously set to tomatoes.

Report on the treatment of apple scab, 1898. F. D. CHESTER

(*Delaware Sta. Rpt. 1899, pp. 27-30, dgm. 1*).—In continuation of previous investigations, the fourth year's report is given of spraying experiments conducted on Winesap and Strawberry apple trees. Bordeaux mixture, composed of 6 lbs. of copper sulphate, 6 lbs. of lime, and 50 gals. of water, was applied to the trees, the first application being made when the buds were swelling, the second just after the petals had fallen, and the third at the time the fruits were about the size of peas. At the third spraying 4 ozs. of Paris green was added to each barrel of fungicide.

The effect of the spraying, as shown by the yield of Winesap apples, is reported, the Strawberry apple trees not having produced any fruit. At the close of the season the Strawberry apple trees had produced an abundance of fruit buds, with good foliage, while the unsprayed trees had lost their leaves and were in poor condition. The yield of the Winesap apples is tabulated, from which it appears that the trees receiving 3 sprayings bore 68.2 per cent first class, 16.6 per cent second class, and 15.2 per cent third class fruit which were badly scabbed, while the unsprayed trees produced 14.7 per cent first class, 33.1 per cent second class, and 52.2 per cent third class fruit.

Peach-leaf curl, its nature and treatment, N. B. PIERCE (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 20, pp. 204, pls. 30, figs. 10*).—The author's investigations show that peach-leaf curl has a widespread distribution and in humid localities is a hindrance to peach culture. The disease is caused by the parasitic fungus, *Ercosens deformans*, the ravages of which are largely dependent upon the atmospheric conditions prevailing while the trees are leafing out. Rains and cold weather at that time increase the severity of the disease by favoring the growth of the parasite. For this reason, orchards near large bodies of water and in low, damp situations are more subject to leaf curl than those in dry regions or elevated situations. An extensive account is given on the life history of the fungus causing the disease. The mycelium of diseased leaves is found to be connected through the leaf petiole with the mycelium of the infected limb. Much of the spring infection probably occurs through the wintering mycelium of the branch, but this is not considered the common mode of infection of the leaves. It seems that most of the spring infections of the peach occur from spores that winter on the tree and about the newly formed buds, and most of the infected leaves fall off without infecting the branch which bears them. The mycelium of badly infected leaves sometimes passes into the branch and this mycelium in some instances may follow the branch for 1 or, at most, a few internodes and possibly infect some adjoining buds. Badly infested branches usually die during the year, while in a comparatively few instances they may support a living mycelium capable of inducing spring infection upon opening buds. Most of the spring infections

are due to the spores of the fungus and not to a perennial mycelium as was formerly believed.

Leaf curl has been successfully treated since about 1880 and copper sulphate sprays are found to be more effective than sulphur or other fungicides. On the whole, Bordeaux mixture in the proportion of 5 lbs. of copper sulphate, 5 lbs. of lime, and 45 gal. of water, gives the best results. This should be applied shortly before the opening of the fresh buds. In this way 95 to 98 per cent of the spring foliage may be saved. By thorough spraying with Bordeaux mixture, gains of \$427.80 per acre are recorded where trees were planted at distances 25 ft. each way. The trees should be sprayed each season, as the experiments prove that treatment one season may not prevent disease the following year. The proper time for winter spraying and the number of applications depend on the locality, season, etc., but the most good is likely to follow if applied from 1 to 3 weeks before the opening of the blossoms in the spring. A proper time to apply the spray is in calm weather, during the middle of the day. Of nearly 200 varieties of peach and nectarine examined, it was found that very few were wholly free from this disease, while some were very subject to it; but it was demonstrated that a single winter treatment will prevent disease even upon those varieties which are most subject to it.

Treatment for the prevention of brunissure, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 47, pp. 637, 638).—An account is given of experiments to combat brunissure in vineyards whose yield of grapes had greatly depreciated on account of this disease. In October, 1898, the vines were given a thorough spraying with a 30 per cent solution of iron sulphate. In November a fertilizer composed of sulphate of potash, superphosphate of lime, and plaster was given the different vines, followed in March by an application of nitrate of soda. A second spraying was given, in which a 20 per cent solution of iron sulphate was used. In 1899 the vines which had received this treatment were much more vigorous than the others, and the yield was materially increased, although the disease had not entirely disappeared. A similar treatment was given them in 1900 with very satisfactory results, the disease having almost entirely disappeared on the treated vines, although abundant on those not having been given any preventive treatment.

Carnation-stem rot, F. W. CARD and G. E. ADAMS (*Rhode Island Sta. Rpt.* 1899, pp. 131-135).—A series of experiments are reported upon which were conducted in 1899 with the hope of ascertaining methods for caring for carnations which are attacked by stem rot caused by different species of fungi. Fifteen hundred cuttings of a very susceptible variety (Flora Hill) were secured and divided into lots of 100 each and submitted to different treatments. Healthy and diseased cuttings were grown in clean sand and sand on which carna-

tions had been previously grown. Chemical fertilizers and stable manures were compared, and the effect of dipping cuttings in Bordeaux mixture before planting was tested. The results of the different treatments are given at some length, but definite conclusions are not warranted from the experiments of a single season.

The most marked results were obtained in the use of fresh clean sand. Dipping the cuttings in Bordeaux mixture before placing in the cutting bed was attended with considerable loss, so that it is believed such treatment is unsafe. The general belief that stable manure in the soil favors the progress of the disease was not sustained in the trials made by the authors. The most important points for practice brought out by their experiments seem to be the superior value of sand and soil in which carnations have not been previously grown. It is said that one of the species of fungi causing the disease is believed to be the same as that producing the rot of sugar beets and the damping off of other plants. Should this prove true upon further examination, soils where such plants have been grown should not be used for growing carnations.

Botrytis and Sclerotinia: Their relation to certain plant diseases and to one another, R. E. SMITH (*Bot. Gaz.*, 29 (1900), No. 6, pp. 369-407, pls. 3, figs. 3).—A report is given of several years' investigation of a disease of hothouse lettuce, and incidentally diseases of a number of other plants are mentioned and described. In the course of the author's studies it became apparent that there were different forms of lettuce diseases, all of which were generally characterized by the name of lettuce rot. The first form described is characterized by a soft, dark, decayed spot on the stem of the plant near the surface of the soil. This spreads rapidly, penetrating the stem and involving the bases of the lower leaves. With further progress of the decay, the center of the head becomes attacked and soon collapses into a fetid, slimy mass. Plants growing finely and approaching maturity suddenly collapse; the stem at the surface of the ground and the bases of the leaves are found to be rotted, and in a day or two the plant is completely gone. This form of disease is what the author characterizes as the *Botrytis* type and is due to *Botrytis vulgaris*. A second form, known as the no-*Botrytis* type, is far more common. In this disease no conidial form has ever been found. In general effect the disease is similar to that already described and is entirely indistinguishable from it. Affected plants wilt and collapse, and in a few days are entirely destroyed. Associated with the usual mycelium in the stem is an abundant white, woolly mycelium proceeding from the affected plants to the surrounding cell, where it flourishes luxuriantly, often spreading to and attacking adjacent plants. No reproductive bodies could be obtained, but infection experiments were easily performed by the

use of diseased tissue or masses of mycelium. The results obtained in these experiments show that the cause of this disease is an active parasite capable of causing the disease at any age of the plants, but at the same time the organism is able to flourish under purely saprophytic conditions. It was found that sterilizing the soil to a depth of 3 in. completely prevented the occurrence of this type of disease.

The third type in its effect upon the host is similar to those just described, but no *Botrytis* appeared. From the sclerotia placed in wet sand numerous trumpet-shaped *Peziza apothecia* appeared, and the fungus was determined as a typical form of *Sclerotinia libertiana*. The author's conclusions are that the lettuce "drop" in Massachusetts is caused by 2 distinct species of fungus, *Botrytis vulgaris* and *Sclerotinia libertiana*. These 2 fungi are remarkably alike in many respects, and have a similar effect upon the host plant. Most of the diseases were caused by degenerated forms of *Sclerotinia* which have almost entirely lost the ability to reproduce themselves by spores and have become highly specialized as a vegetative facultative parasite. The disease caused by *Botrytis vulgaris* and the typical form of *Sclerotinia libertiana* in mature plants is rare.

Notes are given on a number of diseases which have been attributed by different authors to *Sclerotinia* and *Botrytis*. Among those described are diseases of hemp, rape, potato, cucumber, and various rots of vegetables and fruits. Of diseases due to *Botrytis* alone the author describes a new disease of the linden, in which the branches and upper part of the stem show no abnormal symptoms, while the lower part from the surface of the ground to a height of several inches showed numerous excrescences breaking through the epidermis. This disease seems to be, as far as the author's observations go, a nursery stock disease that results in the bark of the lower part of the stem being destroyed and the wood laid bare. It is believed that this disease is caused solely by *Botrytis cinerea*, which in this case is a true parasite. A disease of rose twigs in hothouses, due to *Botrytis*, is briefly described, and a number of other diseases due to this group of fungi is mentioned.

The author concludes that there is no connection whatsoever between *Sclerotinia libertiana* and *Botrytis cinerea*. The connection between the 2 species which has been frequently claimed is due to their simultaneous occurrence and similarity of mycelium as well as their effect on the host.

Two diseases of red cedar, caused by *Polyporus juniperinus* n. sp. and *P. carneus*, H. VON SCHRENK (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 21, pp. 22, pls. 8*).—Examination was made by the author of the cause of a diseased condition noticed in the wood of the red cedars of the United States, *Juniperus*

virginiana and *J. barbadensis*. Hitherto but few diseases of the red cedar have been described, the most important being the so-called cedar apples, due to a species of *Gymnosporangium*.

The mycelia of 2 fungi were observed growing in the heartwood of many trees and bringing about characteristic changes which rendered the wood unfit for lumber. A study conducted in central Tennessee and southern Missouri showed that these 2 forms of decay were present in each region. The most striking form is one called white rot of the red cedar, due to *Polyporus juniperinus*. It causes long holes in the heartwood, which often unite, making tubes through the entire trunk. At first the holes are separated by long stretches of wood which is apparently unchanged, but closer examination shows this wood is of a reddish-brown color instead of the deep red of sound wood. The holes are lined with a brilliant white coating, which consists of almost pure cellulose of the original wood, the incrusting lignin substances having been removed. In the larger holes the amount of wood fiber which has been reduced to cellulose is very considerable. In the older holes the white lining is almost absent, the walls at this time being covered with a felt of soft brown mycelium.

The changes which the fungus causes in the wood are described at considerable length. The fungus apparently enters the trunk through a dead branch and when the hyphæ reach the heartwood they grow both upward and downward. This disease is seldom noticed in trees 25 years old, but is most abundant in those considerably older. A study of the fruiting body of the fungus has shown that it is a new species, and a description is given of it.

The second disease is described as that called red rot, or pecky cedar. This is perhaps more common than white rot and has been observed in cedar trees over a considerable portion of eastern United States and also in specimens received from Bermuda, and has also been observed on arbor vitæ in Maine, where it produces the characteristic brown pockets. Wood affected with this disease is full of these spots. In the early stages these are free from one another and are more or less filled with a brown metamorphosed wood substance, which is cracked so as to form small cubes adhering to the walls of the pockets. The pockets are of different sizes, varying in length from 1 in. to several feet. In cross section they are nearly circular when small but become irregular when old, and frequently a number join together, making large irregular holes full of brown wood which has the appearance and properties of brown charcoal. The line of demarcation between the brown wood and the normal heartwood is very sharp.

The structural changes caused by this fungus are described, as well as the mycelium and fruiting body. Although mature spores have not been found, on account of its flesh-colored hymenium it was regarded as a form of *Polyporus carneus*.

The fungi causing the 2 diseases above described are believed to be wound parasites which grow in the heartwood of living trees, rendering the wood unfit for commercial purposes. Frequently diseased trees are cut and sold as an inferior grade of fence posts, although apparently they last almost as long as sound ones. The natural supply of red cedar still available is very small and any remedies which might be suggested in connection with these 2 diseases must be applicable to trees growing under modern methods of forestry for lumber or ornament. After a tree has once become affected, remedies will not avail.

The more important fungus diseases of agricultural plants and means for their prevention, E. HOTTER (*Die wichtigsten Pilzkrankheiten der landwirtschaftlichen Kulturgewächse und ihre Bekämpfung*. Graz: Leuschner & Lubensky, 1900, pp. 60, figs. 47).

Some parasitic fungi of cultivated plants, G. BRIOSI and F. CAVARA (*I funghi parassiti delle piante coltivate od utili essiccati, delineati e descritti, Fasc. XIII, XIV*. Pavia, 1900; abs. in *Bot. Centbl.*, 84 (1900), No. 1, pp. 14, 15).—In a list of 50 species of parasitic fungi, the authors have described the following new species: *Ovularia medicaginis*, parasitic on alfalfa leaves; *Melogramma henricquetii*, on branches of cork oak; *Ramularia vallisumbrosæ*, on narcissus leaves; *Cercospora ariminensis*, on sulla leaves; *C. helianthemii*, on helianthemum; *C. hypophylla*, on *Rosa canina*; *C. ticinensis*, on leaves of *Sambucus nigra*; *Ascochyta polemonii*, on polemonium; and *Lepothyrium peronæ*, on peony leaves.

Potato and apple scab, G. E. STONE (*Massachusetts State Bd. Agr. Leaflet No. 7*, pp. 4, figs. 2).—A popular description is given of the potato scab, caused by *Oospora scabies*, and the treatment of the seed tubers with corrosive sublimate or formalin solutions recommended. The apple scab, due to *Fusicladium dendriticum*, is briefly described, and as remedies the author recommends 5 sprayings with Bordeaux mixture in which Paris green is added to the second and third for the destruction of the cankerworm, curculio, etc.

The black knot of the plum and cherry, G. E. STONE (*Massachusetts State Bd. Agr. Leaflet No. 3*, pp. 4, figs. 2).—The black knot of the plum and cherry, caused by the fungus *Plowrightia morboza*, is popularly described and remedies suggested. Spraying with Bordeaux mixture and careful attention to orchards, and the removal of all badly infested trees, are recommended.

The black leaf spot of maples, E. MARCHAL and J. HUBERTY (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 1, pp. 1-4, fig. 1).—A description is given of the leaf spot caused by the fungus *Rhytisma acerinum*. This disease usually makes its appearance in Belgium in the month of July and may prove of considerable injury, especially to nursery stock.

An experiment in its prevention is briefly outlined, in which nitrate of soda at the rate of 250 kg. per hectare was used as a fertilizer with decided advantage. The disease was very abundant in maple plantations surrounding the plats, as well as on the check plat, but the area receiving the nitrate of soda remained absolutely free from the disease.

A red mold, R. G. CURTIS (*Proc. Indiana Acad. Sci.*, 1898, pp. 262-268, pls. 4).—Descriptive notes are given in which the characteristics exhibited during the growth of a red mold are described.

Notes on *Aspergillus oryzae*, KATHERINE E. GOLDEN (*Proc. Indiana Acad. Sci.*, 1898, pp. 189-201, pls. 5).—Notes are given on the history, morphology, and physiological characteristics of this well-known Japanese mold. The author's investigations showed, so far as her experiments went, that there was no indication that

A. oryzae has the power of causing alcoholic fermentation or of being transformed through any conditions into a yeast, as has been frequently claimed.

Notes on *Peltandra rust*, F. H. BLODGETT (*Science*, n. ser., 12 (1900), No. 303, pp. 581, 582).—An abstract is given of a paper in which a rust of *Peltandra* is described. The disease was first noticed in the New York Botanical Gardens where some leaves were infested upon nearly every plant. Usually the upper portion of the petiole was most severely attacked. In the worst cases the midrib and its branches and the petiole nearly to the water, would be covered with the rust. In such cases the plants suffered severely from a bacterial rot. The fungus causing this rust is determined as *Cromyrium caladii*.

A new parasite of *Polygonatum*, A. JACZEWSKI (*Hedwigia*, 39 (1900), No. 3, Beihefte, p. 81, fig. 1).—*Cylindrosporium komarowi* is described.

The perithecial form of *Cercospora cerasella* and its development, R. ADERHOLD (*Ber. Dent. Bot. Gesell.*, 18 (1900), No. 6, pp. 246-249).—*Mycospharella cerasella* is described as the perithecial form of *Cercospora cerasella*. It is found on fallen cherry leaves where it winters.

The mistletoe as an enemy to orchard and forest trees, E. S. ZÜRN (*Prakt. Bl. Pflanzenschutz*, 1900, Nos. 3, pp. 19-21; 5, pp. 34, 35).

The resistance of cereal smuts to formalin and hot water, W. STUART (*Proc. Indiana Acad. Sci.*, 1898, pp. 64-70).—Experiments are reported in which the resistance of the smuts of wheat and oats to formalin and hot water was tested. Seed of both these cereals was subjected to hot water treatment at temperatures ranging from 110 to 140° F.; and other lots were soaked in $\frac{1}{4}$ to $\frac{1}{2}$ per cent solution of the formalin, and the effect of the treatment as shown in the germination of the seed and cultures of the fungus spores is given in tabular form. It appears that the spores are much more easily injured than the grain, either when given the hot water or formalin treatment. The essential feature in either treatment is to bring the solution in contact with the seed for sufficient time to enable it to reach the smut spores. The advantage possessed by formalin over hot water lies in the greater ease of its application.

The injurious effects of sulphur upon grapes in strong sunlight (*Hessische Landw. Ztschr.*, 70 (1900), No 42, pp. 584-586).—Rather serious injury to the foliage and fruit of grapes is attributed to applications of sulphur during a period of clear, bright days with a rather high temperature.

ENTOMOLOGY.

Notes on the mosquitoes of the United States, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Bul.* 25, n. ser., pp. 70, figs. 22).—The author discusses the subjects of the abundance of mosquitoes, Alaskan and other far-northern mosquitoes, length of life of the adult mosquito, life history of mosquitoes in general, food of adult mosquitoes, and the distance to which mosquitoes can fly.

Observations were made and experiments conducted to determine how long mosquito larvæ can live out of water or in wet mud. Some cases have been reported where mosquito larvæ are said to have lived in the muddy bed of dried-up ponds for a period of a week or more. Experiments in glass vessels indicated, however, that the larvæ could not live longer than 48 hours in mud. The synoptic tables published in Circular 40 of the Division of Entomology for the identification of mosquitoes in the United States are reproduced. The life history of *Culex* is reprinted from Bulletin 4, n. ser.

The adult of *Anopheles quadrimaculatus* is readily distinguished from species of *Culex* by the attitude of the body when at rest, the position being such as to keep the body in a straight line, whatever the angle made with the substratum may be, and the note of the female which is lower in tone than that of species of *Culex*. The eggs of *Anopheles* are laid in a loose mass floating upon the surface of the water, each egg lying upon its side instead of standing upon its end as in the case of *Culex*. They are not firmly attached together. The larva of *A. quadrimaculatus* remains habitually at the surface of the water. Its breathing tube is shorter than that of *Culex* and its body is held parallel to the surface. The natural food of the larvæ consists of spores of Algæ, minute sticks, and bits of cast larval skins. In the final larval stage of this species the diameter of the thorax becomes much greater than in previous stages as compared with the rest of the body. The generation studied by the author occupied 3 days in the egg stage, 16 days in the larval stage, and 5 days in the pupal stage, making a total period of 24 days in the earlier stages. Natural breeding grounds for this species were found in Maryland, Virginia, and the District of Columbia. Three species of this genus have been recognized in the United States, *A. quadrimaculatus*, *A. punctipennis*, and *A. crucians*. Brief notes are also presented on the genera *Psorophora*, *Megarhinus*, and *Ædes*.

The natural enemies of mosquitoes are the larvæ of dragon flies and the larvæ of Dytiscidæ, Hydrophilidæ, and Gyrinidæ, beside fish, nighthawks, whippoorwills, bats, etc.

Of the artificial remedies for use in houses the best results have been obtained by burning pyrethrum powder, and catching mosquitoes on the walls in kerosene cups, in cases where screening and mosquito bars do not successfully keep out all the mosquitoes. In the destruction of larvæ in breeding places, the use of a kerosene film upon the surface of stagnant pools is again recommended. Permanganate of potash which was heralded in the newspapers as a certain remedy for mosquito larvæ, is thoroughly discredited by experiments. Tar and its compounds have also been recommended, but experiments indicated them to be rather unsatisfactory as compared with the heavier grades of kerosene. The planting of eucalyptus trees in the neighborhood of houses seems to have the effect of keeping the mosquitoes away. The most efficient remedy, however, for the mosquito nuisance is the thorough drainage of all pools in which the larvæ breed.

On the resting position of *Anopheles*, L. W. SAMBON and G. C. Low (*British Med. Jour.*, 1900, No. 2077, p. 1158).—The authors made extended observations on the habits of *Anopheles claviger*, which is said to be the most common species of this genus in Italy. It is maintained that previous statements that standing on its head is a common resting position of this species is incorrect. Species of *Culex*

and Anopheles frequently rest with the third pair of legs lifted away from the support. The authors noted that the legs of *A. clariger* were stretched out with the tarsi pointing downward, while those of certain species of *Culex* were curved upward. The habit of resting, with the body at a very wide angle to the substratum, was noted in *A. pseudopictus*. In *A. superpictus* the resting position was the same as in *A. clariger*. The authors state that the resting attitude of these mosquitoes can not be used for the purpose of distinguishing the genera *Culex* and *Anopheles*, but may furnish characters for separating species of *Anopheles*.

Notes on insect pests from the entomological section, Indian Museum, E. BARLOW (*Indian Mus. Notes*, 5 (1900), No. 1, pp. 14-34, pl. 1).—*Sericin assamensis* is reported from Assam as destructive to tea plants. The author gives a brief description of this beetle. The insect occurs in large numbers and commits serious depredations upon tea plantations. Experiments conducted by tea raisers indicate that ordinary insecticides are not very effective against this beetle. *Heterusia cingala* depredates upon the tea plant. A Tachinid parasite, *Exorista heterusia*, was bred from this insect.

Hispia senescens is reported as destructive to rice crops. The insect makes its appearance in June and July. It attacks first the leaves and later the heads. *Epacromia dorsalis* is reported as an enemy to the young wheat crop in Bombay and other parts of India. *Hieroglyphus furcifer* is another grasshopper which is said to be very injurious to rice and grass crops.

Brief economic and biological notes are given on the sorghum borer moth (*Chilo simplex*) and *Heliothis armigera*.

Detailed tables are given showing the amount of damage done by locusts, especially by *Acridium peregrinum*; and brief accounts of insects injurious to mango trees, grapes, teak trees, and sal trees.

Experiments in rearing the San José scale, L. REH (*Bot. Mus., Abt. Pflanzenschutz, Hamburg*, 2 (1899-1900), pp. 21, fig. 1).—In order to rear the San José scale upon American apples, it is necessary to have sound, fresh apples which will remain fresh until after the reproductive period of this insect. Beside these conditions, a suitable temperature must be maintained. The author made observations upon 54 larvæ which were reared from San José scale upon apples. These larvæ issued in May, June, July, and August. The greater number of them were found in May. He studied the distribution of these larvæ upon the apple, and found that 38 per cent crawled into the basin of the apple, and 62 per cent into the cavity at the stem end. Detailed notes are given on the appearance of the larvæ in different stages, the secretion of the scale, and the loss of locomotion. The author observed that the old females shed their scales and secreted masses of a white woolly substance 2 or 3 days previous to the begin-

ning of the reproductive period. The majority of larvæ reared in this manner fails to come to maturity, partly for the reason that the apples begin to decay and fungus mycelia interfere with the life of the larvæ. Two stages were distinguished in the life of the sessile protected larvæ; one in which the appendages assisted the animal in locomotion, and a second in which the soft parts of the appendages were resorbed and the appendages became immovable. The author believes that more emphasis should be laid on the fact that the exuviae contribute to the formation of the permanent scale, and that 2 independent scales are formed out of wax previous to this time. A bibliography of the subject is appended to the article.

Field experiments with the strawberry root aphid, G. H. POWELL (*Delaware Sta. Rpt. 1899, pp. 157-162*).—A number of experiments were conducted with remedies against the strawberry root aphid. Infested strawberry plants were dipped in a strong solution of tobacco water before being set in the field, with the result that no apparent effect was produced on the root aphid. Experiments were tried to determine the effect upon the root aphid of fertilizing soil with muriate of potash, kainit, and tobacco. Kainit was applied in quantities varying from 500 to 1,250 lbs. per acre, muriate of potash from 150 to 600 lbs., and tobacco from 500 to 2,000 lbs. The results of this experiment indicated that it is unsafe to apply muriate of potash to strawberry plants in rows; that not more than 750 lbs. of kainit should be applied to the acre; that no injury resulted from the tobacco dust; and that the different treatments had no effect on the multiplication of the insect.

In another experiment the surface soil was removed from the sides of several infested rows and the trenches thus formed were filled with tobacco dust and covered with soil. Upon examination a month later, after copious rains had fallen, no effect was noted on the aphid. Experiments were tried in scattering tobacco dust over the strawberry plants and on the soil for from 3 to 4 in. each side of the row. Applications of tobacco dust were made in April, June, July, and August. As no decrease in the number of aphid was noted, even where tobacco had been applied at the rate of 1 ton per acre, the experiment was abandoned.

In 1898, a piece of ground at the experiment station, which was infested in 1897, was planted with Lima beans and cowpeas. In 1899, this ground was again set in strawberries. The rotation of crops had the effect of greatly reducing the seriousness of infestation.

Brief notes are given on the life history and habits of this insect, but the life history is thus far not worked out completely. The experience of strawberry growers indicated that the most serious infestation occurs on land that has been planted to corn during the previous year. An apparent explanation of this fact is to be found in the

agency of ants in spreading infestation by the aphid. The same species of ants attend on the corn aphid and strawberry root aphid.

The currant gall mite (*Phytoptus ribis*), DUKE OF BEDFORD and S. U. PICKERING (*Woburn Expt. Fruit Farm Rpt. 1900, pp. 7-34, figs. 4*).—Experiments with insecticide treatments against this insect were made by the authors with the assistance of Miss Ormerod and Mr. Newstead. The mites are found in large numbers in each infested bud, 3,000 being found in some buds. This species is so minute that its transportation by wind and other agencies is rendered comparatively easy. Its period of activity extends apparently over the whole season during which currants bear leaves. During the time that the mite is inclosed in the bud it is well protected from the action of insecticides. In 1896 Baldwin Black currants showed signs of being infested by the mite and the galls were removed. The infestation increased, however, during the next year and extended to the Black Naples currant. The galls were again removed, but a further increase in infestation was noticed the following year. Although the affected buds were removed each year, the number of infested buds on the currant bushes was doubled in 1 case and increased fourfold in another. The method of removing the infested buds seems, therefore, to promise little success. In the first series of experiments with insecticides from December, 1897, to October, 1898, each experiment involved 30 bushes in a double row subjected to the same treatment. All liquid insecticides were applied from a rose can or spraying apparatus. Some of the bushes were lifted and dipped bodily into some insecticide, while still others were painted with the insecticide. The insecticides which were used included carbolic acid 0.8, 1.6, and 2.4 per cent, calcium sulphate 1.5, 3, and 4.5 per cent and mixed to the consistency of paint, 3 qts. to 10 lbs. of clay, kerosene emulsion in a number of strengths, Antinonin, and turpentine. One week after each treatment twigs from bushes in all experiments where insecticides had been used at their maximum strength were subjected to microscopical examination. The results for the most part were of a negative character. Bushes treated with Antinonin were reported to have been infested with the greatest number of mites on February 26, while on March 22 similar observations were made as to both mites and eggs on bushes treated with Antinonin. On April 22 currant bushes which were treated with the strongest Antinonin and carbolic acid showed about 50 per cent of the mites dead. On August 20 following the bushes which were treated with the strongest Antinonin and strongest carbolic acid were reported to be free from mites. In all other cases the mites were found to be swarming with the single exception of bushes treated with turpentine. The success with turpentine, Antinonin, and carbolic acid was, however, only apparent, since the currant bushes were killed by the insecticides. Currant bushes sprayed with the strongest

solution of calcium sulphid were badly affected. Petroleum emulsion was less injurious than any of the other insecticides. In cases where the bushes were lifted and dipped in solutions of carbolic acid or calcium sulphid of various strengths, the results were equally unpromising.

Another series of experiments was carried on from December, 1898, to October, 1899. Each experiment involved 60 currant bushes, half of which were Baldwins and half Black Naples. The substances employed in these experiments were undiluted methylated spirits, naphtha and saturated solutions of naphthaline in naphtha, formalin in 2, 0.5, and 0.1 per cent solutions, undiluted kerosene, and kerosene emulsion in 2 strengths. In none of these experiments did the insecticide treatment have any effect on the mites. No appreciable effect on the foliage was produced by the methylated spirits, naphtha, naphthaline, or formalin. In the use of kerosene emulsion it was noted that so long as weaker grades were used, the injury to the foliage was greater as the strength of the solution increased. When much greater strengths were used, there was much less injury, and in the case of pure petroleum there was no injury whatever to the foliage. The authors explain this result by the insolubility of kerosene in water, the coating of moisture on the leaves preventing it from coming into direct contact with the leaf tissue. An increase as well as a decrease in the strength of the kerosene emulsion beyond a certain point may render the emulsion less injurious to the foliage and also less destructive to insects.

A series of experiments was conducted for the purpose of determining whether this species of mite may not find shelter in the ground or about the roots of currant bushes as well as in the buds. The experiment showed conclusively that the mite does not hibernate anywhere except in the buds and that infestation may often be due to transportation of the mites by wind. The authors experimented with hydrocyanic-acid gas during which 1 oz. of potassium cyanid, 1 oz. of sulphuric acid, and 2 oz. of water were used for every 150 cubic feet of space. In order to confine the gas the plants were covered with a box which was inclosed with tarred felt. After this treatment the mites were found to be uninjured. Another insecticide, consisting of a solution of nicotin and camphor in diluted alcohol, was tried with negative results. Dipping currant bushes in water at various temperatures was found to furnish a rather efficient means for destroying the mites. A 5 minute immersion in water at 115° F. destroyed the adult mites but did not destroy the eggs. Higher temperatures, such as 140 or 160° F., were found to produce disastrous effects upon the currant bushes. A general inspection of infested bushes disclosed the fact that in any particular variety the infestation by mites was most pronounced in the strongest and healthiest bushes.

Of the varieties which the authors had under observation, Baldwin was perhaps most infested, while the Old Black was least infested. The authors conclude that until an immune variety is produced the best means of eradicating the pest appears to be wholesale cutting down of all bushes on any plantation which has become infested and burning them on the spot.

Bees and the fruit grower (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 5, pp. 285-287).—A popular discussion of several problems concerning the relationship of bees to fruit.

Swarm catching and hiving, A. GALE (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 878-881).—Practical notes on the habits of swarming in bees and on methods of securing and hiving swarms.

Races of Caucasian bees in connection with the general problem of the races of bees, G. A. KÖZHEVNIKOV (UIM) (*Porodni karkozskikh pchel v svyazi k voprosu o porodakh pchel roobshche*. St. Petersburg, 1900, pp. 24, pl. 1).—The author discusses the peculiar characteristics of Caucasian varieties of bees as compared with many varieties of other regions.

Directions for the reeling of silkworm cocoons, V. P. IVONOV (*Nastavlenie k razmotkye kokonov*. Tiflis, 1899, pp. 35).

A list of works on North American entomology, N. BANKS (*U. S. Dept. Agr., Division of Entomology Bul.* 24, n. ser., pp. 95).—This bulletin contains a list of comprehensive works most useful for the study of North American insects; works on bibliography; and systematic works on single orders, including Hymenoptera, Diptera, Lepidoptera, Coleoptera, Hemiptera, Orthoptera, Neuroptera, Mallophaga, Thysanura, Myriapoda, and Arachnida; works on economic entomology; publications of the U. S. Entomological Commission and Division of Entomology; and important periodicals containing articles on entomology.

The asparagus fly and means of combating it, P. GRÜNDLER (*Atti Mem. Ital. R. Soc. Agr. Gorizia*, n. ser., 40 (1900), No. 10, pp. 325-328, figs. 2; trans. from *Landw. Ztschr. Oberösterreich*, 1900, No. 12).—The asparagus fly (*Trypeta fulminans*) lays its eggs in the substance of young asparagus plants, especially under the scales. The larvæ which hatch from these eggs burrow in the substance of the plants. The treatment for these insects which is recommended by the author is spraying with Paris green.

Another enemy of the sugar cane (*Trinidad Bot. Dept. Bul. Misc. Inform.* 25, 1900, p. 289).—*Rhynchophorus palmarum*, commonly known as the palm beetle, is reported as attacking canes growing in the station grounds at St. Clair. The larvæ made a burrow completely through the cane from top to bottom, destroying all the soft inner portion. This beetle is rather common in Trinidad and usually attacks palms. It is not believed that the habit of injuring sugarcanes will become general.

The principal insects affecting the tobacco plant, L. O. HOWARD (*U. S. Dept. Agr., Farmers' Bul.* 120, pp. 32, figs. 25).—A revised edition of the author's article in the Yearbook for 1898 (*E. S. R.*, 11, pp. 471, 472).

Insects injurious to the apple tree with suggestions as to their control or extermination, J. M. SOUTHWICK (*Providence: Rhode Island State Bd. Agr.*, 1900, pp. 12).—Brief popular notes on a considerable number of insects injurious to the apple tree.

The reappearance of the elephant beetle, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 847-851).—*Orthorrhinus cylindrirostris* is reported as injurious to grapevines, orange trees, apple trees, chestnuts, etc. The eggs are deposited in the substance of the bark. The larvæ upon hatching burrow downward into the main roots and then retrace their course to a point near where the egg was deposited and here pupate. Since there is no open passage into the burrow of this

insect, the remedies usually applied in such cases are not effective against the elephant beetle. Hand picking and jarring are to be relied upon to reduce the numbers of the beetle.

Practical suggestions for combating the coffee borer (*Planting Opinion*, 5 (1900), No. 40, pp. 687-689).—Planters usually adopt a method of cultivating shade to protect coffee plants against the attacks of *Xylotrechus quadripes*. If affected coffee trees are to be burned for the purpose of destroying the insect, this measure should be adopted before the insect has escaped, or previous to April 15. The author recommends that the adult insects should be caught by systematic efforts extending over the whole season during which they may be found. It is also recommended that the stems of coffee bushes be scraped and cleaned. The borer requires fissures in the bark for the purpose of depositing its eggs, and egg laying would thus be rendered difficult by making the surface smooth.

Calcium carbide as a remedy for phylloxera, F. VASSILIÈRE (*Bul. Agr. Algérie et Tunisie*, 6 (1900), No. 18, pp. 538, 539).—From experiments made by the author it is concluded that calcium carbide applied at the base of the grapevine in the form of powder, or in small fragments, constitutes a very valuable remedy against phylloxera.

On the cause of the resistance of American vines to phylloxera, V. PÉGLION (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 4. ser., 23 (1900), No. 2, pp. 183-241).—This article constitutes an historical and critical discussion of American vines in America, the hereditary transmission of resisting power to phylloxera, injuries of the root system in relation to the resisting power, and the determination of the degree of resistance. A bibliography of the subject is appended.

The gall of the Monterey pine, W. A. CANNON (*Amer. Nat.*, 34 (1900), No. 406, pp. 801-810, figs. 6).—*Pinus radiata* growing on the grounds of the Leland Stanford Junior University was severely attacked by a species of gall gnat. The gall consisted of a malformation of the leaves. The gnat larvæ were found in pockets of the swollen leaves, entirely surrounded by vegetable tissue. In the fall such leaves contain 4 or more larvæ. In February eggs were to be found deposited between the leaf fascicles, on the outside of the young shoots, and between the scales. In consequence of the presence of the larvæ, the epidermis of the scales and leaves was modified in structure and function. The hypertrophy of the vegetable tissue was apparently not caused by any substance deposited with the eggs.

A contribution to our knowledge of the spiders of Victoria, including some new species and genera, H. R. HOGG (*Proc. Roy. Soc. Victoria*, 13 (1900), No. 1, pp. 68-123, pls. 5).—Brief biological and economic notes on a number of species of spiders, together with descriptions of new species.

Regulations of foreign governments regarding importation of American plants, trees, and fruits, L. O. HOWARD (*U. S. Dept. Agr., Division of Entomology Circ.* 41, 2. ser., pp. 4).—This circular contains a brief statement of the requirements regarding shipments from America to Austria-Hungary, Belgium, British Columbia, Canada, Cape of Good Hope, France, Germany, Netherlands, New Zealand, Switzerland, and Turkey. A list is given of places at boundary lines of different countries where plants may be introduced.

Physiological test of hydrocyanic-acid gas on strawberry plants, G. H. POWELL (*Delaware Sta. Rpt.* 1899, pp. 162, 163).—Experiments were made for the purpose of determining the effect of hydrocyanic-acid gas on strawberry plants, during which 1,500 Brandywine and Bulach strawberry plants were fumigated in a box containing 60 cubic feet of space. At the time of treatment the plants were moist. The period immediately succeeding the setting of the plants was unusually hot and dry. The results of the experiments indicate a slight injury to all the plants. The application of 0.1 or 0.2 gm. of cyanid of potash per cubic foot for 10 minutes did but little harm.

FOODS—ANIMAL PRODUCTION.

A report of investigations on the digestibility and nutritive value of bread, C. D. WOODS and L. H. MERRILL (*U. S. Dept. Agr., Office of Experiment Stations Bul. 85, pp. 51*).—The authors report the details of a number of experiments with healthy men on the digestibility of white bread, whole-wheat bread and graham bread. In some cases the bread was eaten alone, in others materials such as milk, sugar and butter were eaten in addition. With a view to learning the actual amount of nutrients digested, 2 methods of studying the metabolic products in the feces were investigated, namely, (1) treatment with a pepsin solution, and (2) with ether, alcohol, hot water and cold lime-water. The metabolic nitrogen in the feces on a carbohydrate diet and during fasting was also studied. Artificial digestion experiments with 3 sorts of bread were made; the value of skim milk & water in bread making was tested, and the loss of materials in bread making was investigated. The average coefficients of digestibility of the different sorts of bread and the digestibility of protein as shown in the artificial digestion experiments and when corrections are made by the 2 methods of estimating the metabolic products are shown in the table which follows:

Average digestibility of bread of different kinds.

	Total organic matter.	Protein.				Fat.	Carbohydrates.	Heat of combustion.
		Natural digestion.	Artificial digestion.	Natural, corrected by method 1.	Natural, corrected by method 2.			
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
White bread	96.0	85.41	93.26	94.72	90.67	73.5	98.3	91.1
Entire wheat bread.....	95.7	88.63	91.49	96.22	90.37	57.8	97.2	89.6
Graham bread	91.0	77.02	86.97	91.58	83.88	58.1	92.4	84.4

When skim milk and water were compared for bread making, it was found that the skim-milk bread contained somewhat more protein than the water bread. As shown by methods of artificial digestion there was little difference in the 2 sorts of bread. The results obtained in studying the losses of material in bread making are not discussed at length.

Experiments on the preservation of meat and fish with salts, E. PETTERSSON (*Arch. Hyg., 37 (1900), No. 2-3, pp. 171-238*).—Bacteriological studies are reported of meat and fish preserved with different strength solutions of salt, saltpeter, boric acid, and borax. The experiments are discussed in detail. Among the conclusions are the following: The principal effects of common salt as a general preservative are the retarding of the growth of micro-organisms, hindering even when present in a weak solution the deep-seated decomposi-

tion of protein, and the diminution of the chemical activity of certain micro-organisms.

Saltpeter, even when mixed with a small quantity of salt, prevents for a long time the formation of hydrogen sulphid, and, therefore, in the author's opinion, is useful in pickling meat and fish. Boric acid was found to be a satisfactory means of checking the growth of rod-like forms and cocci. However, it did not check the growth of yeasts. Borax was found to be a very active agent for checking bacterial growth. Even when mixed in small quantity with salt it materially increased the keeping quality of the materials preserved. For other reasons, however, the author does not recommend the use of borax and boric acid.

Contribution to the estimation of assimilable protein in feeding stuffs, K. BULOW (*Jour. Landw.*, 48 (1900), No. 1, pp. 1-38).—In order to study the true digestibility of nitrogen, digestion experiments were made with sheep by the usual method, and the feces were treated by the Kühn method of artificial digestion with pepsin and by the Stutzer method with pepsin and trypsin. The different feeding stuffs were also digested artificially by the Kühn and Stutzer methods. The effect on digestibility of rapid drying of feeding stuffs was also tested. The following table summarizes the average results of the different tests:

Digestibility of nitrogen of feeding stuffs estimated by different methods.

Feeding stuffs.	Total nitrogen.					Albuminoid nitrogen.				
	Appar- ent di- gesti- bility.	Digestion as corrected by—		Artificial diges- tion by—		Appar- ent di- gesti- bility.	Digestion as corrected by—		Artificial diges- tion by—	
		Pepsin meth- od.	Trypsin meth- od.	Pepsin meth- od.	Trypsin meth- od.		Pepsin meth- od.	Trypsin meth- od.	Pepsin meth- od.	Trypsin meth- od.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Meadow hay No. 1..	51.35	69.32	83.05	66.92	77.69	39.74	62.04	79.03	59.05	72.38
Meadow hay No. 2..	53.33	72.07	86.48	67.15	80.29	45.83	67.57	84.31	61.86	77.12
Clover hay	65.21	79.06	88.34	76.02	84.55	48.43	68.96	82.72	64.46	77.11
Wheat bran	74.05	88.74	89.85	90.21	92.31	68.42	86.23	87.70	88.14	90.68
Meat meal	95.16	97.41	99.02	95.47	97.99	94.97	97.25	98.98	95.26	97.89
Poppy-seed cake ...	87.39	93.62	95.60	88.60	92.55	85.49	92.66	94.89	86.89	91.43

The author's principal conclusions follow: Treating samples of feeding stuffs and feces with pepsin solution according to Kühn's method rendered the maximum amount of available protein soluble. A portion of the nitrogen remaining after such treatment is rendered soluble by an alkaline trypsin solution. Drying the feeding stuffs renders a portion of the protein insoluble in digestive juices; therefore the drying of feeding stuffs before samples can be ground for analysis should be conducted at a temperature not exceeding from 55 to 60° C. The results of the Stutzer-Pfeiffer method of estimating the digestibility of protein does not agree with the results obtained in actual experiments with animals. The pepsin-trypsin method gives too high results,

while those obtained under experimental conditions with only 250 cc. of pepsin solution were too low. The Kühn method of artificial digestion, on the other hand, shows the amount of protein which is actually soluble in the intestinal tract. This method does not do away with the necessity of natural digestion experiments, but is of value when rapid results are desirable, and under other conditions. The accuracy of the Kühn method has been shown by comparison with results of experiments with ruminants. Whether the method is equally applicable for comparison with mammals, especially man, must be determined by additional experiments.

Forage value [of the Golden Vine field pea] (*Utah Sta. Bul.* 69, pp. 328-340).—Artificial digestion experiments were made with the whole plant, leaves, stalk, and flower, of the Golden Vine field pea, and the results discussed, as well as the food value of this plant and other related topics. The digestibility of the protein of the whole plant varied from 68.21 to 73.99 per cent; that of the albuminoids, from 56.57 to 63.07 per cent. The digestibility of the protein of the leaves varied from 65.05 to 75.95 per cent; that of the albuminoids, from 56.55 to 63.82 per cent. The range in digestibility of the protein in the stalks was from 61.03 to 80.22 per cent; that of the albuminoids, from 49.51 to 62.18 per cent. In the case of the flowers, the digestibility of the protein ranged from 62.68 to 81.88 per cent; that of the albuminoids, from 59.02 to 78.88 per cent.

According to the author the digestibility of albuminoids is practically the same in the whole plant, leaves, and stalks. When just coming into flower, the coefficient of digestibility of this constituent is about 62, the greatest variation being about 4.8 per cent in the whole plant, 5.7 per cent for the leaves, 12.7 per cent in the stalks, and 19.86 per cent in the flowers and pods. The total protein is more digestible than the albuminoids and the variation is also greater. In the whole plant the variation is about 7 or 8 per cent; in the leaves, 10.9 per cent; in the stalks, 19.2 per cent, and in the flower and pods, 19.2 per cent. The leaves were found to contain 7.68 per cent nuclein; the stalks, 2.56 per cent. The protein of the Golden Vine field pea is considered slightly more digestible than that of alfalfa, being most digestible when the plant is just coming into flower. It is more digestible in the stalks than in the leaves. In the flowers a great increase in digestibility of protein occurred simultaneously with an increase in percentage of nitrogen-free extract. Pound for pound pea-vine hay appears to be more valuable than lucern hay. The facts point to early bloom as being the most suitable time to cure for hay. The loss of nutrients, especially protein, after early bloom is very conspicuous.

Feeding with Florida feed stuffs, H. E. STOCKBRIDGE (*Florida Sta. Bul.* 55, pp. 215-308, pls. 11, figs. 2, dgms. 2).—The conditions

which govern stock feeding in Florida are described, the general principles of feeding discussed, and feeding tests reported with steers and pigs and on the digestibility of cassava by a steer. Some Florida feeding stuffs were compared with 3 lots of local range steers and 1 lot of 3 grade steers. Lots 1 and 4, the latter being grade steers, were fed hay, cotton-seed meal, and cassava, about in the proportion of 2:1:7, the ration containing 36 lbs. of cassava per thousand pounds live weight. Lot 2 was fed cotton-seed hulls and meal, 5:1, while lot 3 was fed hay (either pea vine, or a mixture of crabgrass, beggar weed, and cowpea), cotton-seed hulls, wheat bran, and corn meal 3:7:8:7. In 70 days the average daily gains made by the 4 lots were, 2.43, 2.41, 1.95, and 1.83 lbs., respectively. The steers were slaughtered, the dressed weight of the 4 lots being 56.23, 54.55, 54.31, and 55.78 per cent, respectively, of the live weight, the hind quarters constituting in the several cases, 46.36, 49.39, 48.10, and 46.78 per cent of the total dressed weight. It is said that the beef was considered excellent in a local market where it was sold. The profits per lot were \$28.75, \$23.81, \$11.57, and \$25.41, respectively.

The authors point out that the greatest gains were made on the rations containing cassava, and that the native grade steers made greater gains than grade animals, although the latter furnished the largest proportion of hind quarters and the heaviest net weight.

In the feeding test with pigs 4 lots (1 lot containing 1 animal, the others 4 each), of Florida razor-back pigs, and 1 lot of 4 crossbred animals were used. Lots 1 and 2 (the former being the crossbred pigs) were fed cassava, wheat middlings, and cowpeas, 4:2:1.5; lot 3, corn and wheat middlings, 2:3; lot 4, sweet potatoes and wheat middlings, 1:1, while lot 5 was fed corn only. All the pigs weighed not far from 100 lbs. each at the beginning of the test and in 45 days the total gain per pig in the 5 lots was, 72.8, 32.5, 40, 31.6, and 25.9 per cent, respectively; the cost of the gains in the several cases being, lot 1, 2.9; lot 2, 3.1; lots 3 and 4, 5.6 each, and lot 5, 7 cts. The dressed weight ranged from 65.63 per cent of the live weight in the case of lot 5 to 77.53 per cent in the case of lot 1. According to the author, although the results were favorable for fattening razor-back pigs, yet greater gains were made by the blooded pigs. Corn was regarded as a good feeding stuff, but was most satisfactory when given in combination with other feeds.

The digestibility of cassava was tested with a steer on a ration made up of this material, cotton-seed hulls, and cotton-seed meal, about in the proportion of 12:5:1. The usual methods were followed. From the digestibility of the ration as a whole the digestibility of cassava alone was calculated to be as follows: Dry matter 52.12, protein 24.06, fat 59.28, nitrogen free extract 55.47, crude fiber 79.87, and ash 64.96 per cent.

Food and its relation to health, H. SNYDER (*Farm Students' Rev.*, 5 (1900), No. 96, pp. 83, 84).—A general article. Among other points, the author discusses the length of time required to digest foods and the desirability of consuming a mixture of slowly and rapidly digesting foods.

Sugar as food, G. H. MURPHY (*U. S. Consular Rpts.*, 63 (1900), No. 238, pp. 321-324).—A brief statement based on some of the recent European work on the food value of sugar.

Nutritive value of alcohol, W. O. ATWATER (*Harper's Mo. Mag.*, 101 (1900), No. 605, pp. 675-684).—The problem of the nutritive value of alcohol is discussed, the important work of earlier investigators cited, and the author's recent experiments with the respiration calorimeter described in a popular way. Since alcohol is a source of energy in the body, the author considers it a food.

The food value of milk proteids; their properties and use for different preparations, with especial reference to "Eulactol," H. LURIG (*Molk. Ztg.*, 14 (1900), Nos. 29, pp. 493-495; 30, pp. 509-511).—The value of foods prepared from milk proteids is discussed and an experiment with man reported on the digestibility of "Eulactol" when forming part of a mixed diet.

A new skim milk product [Nutrium], (*Farm Students' Rev.*, 5 (1900), No. 6, p. 94).—A food product called "Nutrium" made from skim milk, evaporated and ground is described and an analysis given.

The iron content of egg yolk, SCHMIDT (*Ztschr. Angew. Chem.*, 1900, No. 28, p. 705).—It is reported that the iron content of egg yolk was increased by feeding iron saccharate to hens, and it is claimed that the iron so incorporated in the eggs is more assimilable than most iron preparations.

Preserving eggs, E. F. LADD (*North Dakota Sta. Bul.*, 44, pp. 571-574).—The success attending the preservation of eggs with water glass led the author to reprint an earlier publication of the station (*E. S. R.*, 11, p. 279) on the subject, with a brief introductory statement.

Eggs in cold storage, J. STEPHENSON (*Agr. Gaz. New South Wales*, 11 (1900), No. 7, pp. 551-555).—Methods and results of storing eggs in the Government export stations of New South Wales are treated of.

On the preservation of fresh eggs, H. BORNTAEGER (*Oesterr. Chem. Ztg.*, 3 (1900), No. 12, p. 295).—The author reports the examination of eggs which had been spoiled by an attempt at preservation in weak (10° B \acute{e}) water glass solution which was, however, very alkaline. The eggs absorbed water glass, which rendered the white and part of the yolk gelatinous and as translucent as horn.

The utilization of fruit in Germany (*Sci. Amer. Sup.*, 50 (1900), No. 1282, p. 20549).—This article is based on a consular report discussing the food of the German people, the increasing use of fruit, and the manufacture and regulations governing the production of jams and marmalade.

Compressed yeast—a study of the Boston yeast supply, C. W. PERLEY (*Amer. Kitchen Mag.*, 13 (1900), No. 2, pp. 43-48).—The author examined a number of samples of compressed yeast and determined the amount of carbon dioxid produced by each, the relative number of yeast plants present, and the quality of bread made from different samples of yeast.

Food adulteration in Europe, J. T. DuBOIS (*U. S. Consular Rpts.*, 63 (1900), No. 238, pp. 316-320).—The adulteration of a number of the more common food materials in Europe is discussed.

Food preservatives and coloring matters in food, A. S. GRÜNBAUM (*British Med. Jour.*, 1900, No. 2068, pp. 424, 425).—An address before the sixty-eighth meeting of the British Medical Association, Ipswich, 1900.

The use and abuse of food preservatives, S. RIDEAL (*Sci. Amer. Sup.*, 49 (1900), No. 1270, pp. 20363-20366).—A general discussion which summarizes much experimental work of the author and other investigators. Reprinted from the *Journal of the London Society of Arts*.

The value of grape marc as a feeding stuff, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 39, pp. 389-392).—The composition of grape marc or pomace is quoted and information on the value of this material as a feeding stuff is summarized.

The significance of carbohydrates in muscle, F. S. LEE and C. C. HARROLD (*Science, n. ser.*, 11 (1900), No. 285, p. 952).—Abstract of a paper presented before the New York Academy of Science, Section of Biology, May 14, 1900.

The influence of experimental modifications of the organism on the consumption of glucose, A. CHARRIN and A. GUILLEMONAT (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 2, pp. 126-128).—Experiments with rabbits are reported on the effect of injecting subcutaneously vegetable acids, mineral acids, and sugar solutions.

Concerning metabolism in the horse, T. PFEIFFER (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, pp. 101-112).—A controversial article.

Sheep and wool: A review of the progress of American sheep husbandry, J. R. DODGE (*U. S. Dept. Agr., Rpt. 66*, pp. 63, figs. 3).—The author reviews the history and development of the sheep industry in this country, tracing the history of domestic wool, variations in price, and other questions of commercial importance.

Principles of breeding, A. A. BRIGHAM (*Rhode Island Sta. Rpt. 1899*, pp. 182-198).—A descriptive popular article on poultry breeding.

About foods and feeding, S. BEALE (*Country Gent.*, 15 (1900), Nos. 2463, p. 305; 2464, p. 325).—A general article on poultry feeding.

On the breeding, care, and agricultural value of guinea fowl, E. S. ZÜRN (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 9, pp. 337-340; 10, pp. 372-375).—A general discussion.

DAIRY FARMING—DAIRYING.

Experiments with dairy cows, F. B. LINFIELD (*Utah Sta. Bul. 68*, pp. 167-309, figs. 7, dgms. 9).—A study of the records of the dairy herd for 5 years (pp. 167-237).—The dairy herd consisted of from 7 to 15 grade cows each year for the 5 years. During this time a record of 23 cows for one year or more was obtained. Some of the more important data are summarized in the following table:

Average annual record of dairy herd.

Cow.	Weight of cows.	Time in herd.	Lactation period.	Cost of food.	Yield of milk.	Fat content of milk.	Yield of butter fat.	Yield of butter.	Net returns with butter fat at 16 cts. per pound.
	Pounds.	Years.	Days.		Pounds.	Per ct.	Pounds.	Pounds.	
No. 1	1,332	5	288	\$21.81	5,813	3.2	186.3	217.8	\$8.61

Average	1,020	329	21.43	5,601	4.23	237.0	276.5	16.20

Excluding the 2 poorest cows, Nos. 1 and 6, and 3 heifers, Nos. 17, 18, and 23, the remaining 13 cows gave an average yearly production of 6,019 lbs. of milk and 255.4 lbs. of butter fat, the average returns per cow being \$18.24 over an average cost for food of \$22.21.

A summary of the records by years shows an increase in the average production from 268.6 lbs. of butter in 1894-95 to 286.8 lbs. in 1898-99, with a decrease in the cost of production of 1 lb. of butter from 8.67 to 7.3 cts. These results are attributed to good feed and care, the use of cheaper feeding stuffs, an improvement in the herd due to breeding, and the elimination of a few unprofitable cows.

A study was made of the influence of the weight of the cow, period of lactation, dehorning, methods of feeding, type, and change of milkers upon the yield and quality of milk and the economy of production. Some of the author's conclusions are as follows:

"In the majority of instances the largest production was associated with the lowest live weight, while the least production was associated with the highest weight. A tendency to lay on flesh, therefore, would appear to be opposed to the largest dairy production. . . .

"As the period of lactation advanced the cows decreased in their milk yield about 9 per cent each month. The percentage of fat in the milk increased slightly, more particularly after the sixth month of lactation.

"The effect of turning cows from dry feed to fresh spring pasture was to increase markedly the yield of milk and butter fat and to increase slightly the percentage of fat in the milk. . . . Fresh milch cows gave the greatest increase in yield of milk and butter fat when turned to pasture, but the test of the milk was not affected. . . . Cows changed from dry to green feed in the stable did not give an increase in production like cows turned to pasture. It would seem, therefore, that the increase in production following from the pasture feeding is due mainly to the change in the habits of the cow and in the manner of gathering her food.

"Cows bred to drop their calves during the early winter season, when turned to pasture gave nearly as large a production as when they came in fresh, and they maintained the increased flow on pasture longer than cows that came in at other times. . . .

"A change of milkers may not, as a rule, be advisable, yet a change from a poor to a good milker, even though the good milker was a stranger, showed an immediate increase in milk yield."

Dehorning had no marked effect upon milk production. In a discussion of the type of cow in relation to dairy production, brief descriptions and illustrations from photographs are given of 7 of the cows of the herd.

Data are given showing the variations in the different constituents of the milk of a number of cows, and methods of testing cows and sampling milk at creameries are discussed. "The cows, as a rule, gave less but richer milk from the shorter milking period in the day. . . . The daily variations in the composition of the milk of a cow, the variations from morning to evening, and in the first, last, and average milk, are variations in fat only, and do not, as a rule, extend to the other solids."

Winter feeding experiments (pp. 239-265).—One feeding test was made each winter for 4 years. The first test included 9 cows and covered 24 weeks, and the remaining tests included 4 cows each and covered 16, 19, and 16 weeks, respectively. In each test a comparison was made between alfalfa alone and alfalfa and corn fodder. Different quantities of grain, ranging from 4 to 8 lbs., were fed daily in the different tests. The nutritive ratio of the alfalfa ration was 1:4.6, and of the alfalfa and corn fodder ration 1:6. The results are tabulated and discussed. There was a waste of about 10 per cent in feeding lucern and 25 per cent in feeding corn fodder. The cows gained slightly in weight on the alfalfa ration and lost on the alfalfa and corn fodder ration.

“Calculated from the amount eaten, the ration of alfalfa and corn fodder produced milk and butter fat for a little less outlay in dry matter than the ration of alfalfa, but calculated from the amount fed there was practically no difference. Considering the cost of production, and charging the cows with the amount fed, the corn fodder ration was a little the more costly, but the difference was small . . . The cost of producing milk and butter fat varied according to the amount of grain fed. The ration containing the smallest amount of grain was the most economical. . . . The wider ratio required less dry matter to produce 1 lb. of butter fat, or 100 lbs. of milk.”

Summer feeding experiments (pp. 267-305).—One test was made each year for 4 years to compare soiling and pasturing. In all 9 cows were pastured for about 16 weeks and 9 were fed in the stable on soiling crops for the same time. The pasture-fed cows produced on the average more milk and fat and made a greater gain in live weight than the cows fed in the stable. The flow of milk, however, was not so evenly maintained during the whole period.

A comparison was made in 5 experiments of the results obtained from 1 acre of land when the crop was pastured and when it was soiled.

“One acre of soiling crops furnished feed for 2 cows for 108 days, produced 3,145 lbs. of milk and 147.9 lbs. of butter fat, valued at \$23.67. One acre of pasture furnished feed for 2 cows for 102 days, and produced 4,047 lbs. of milk and 189.8 lbs. of butter fat, valued at \$30.37. This shows an advantage of \$6.50 in favor of the acre of land used as a pasture compared with the same area used for soiling crops. These results are not conclusive, however, for the soiling crops.”

The effect of feeding grain to cows on pasture was studied during 4 years. In all 28 cows were used in the tests, 14 of which were fed 4 lbs. of grain per head daily. The records of the cows fed grain were compared with those of the cows on pasture alone, for the 4 months each summer during which the grain was fed, and also for the 4 months following during which all the cows were fed alike.

“The cows which received grain while on pasture produced more milk and butter fat than those not receiving grain, yet not enough extra to pay for the grain fed. The cows fed the grain on pasture maintained their flow of milk better throughout the milking season than did those not receiving grain, and thus during the fall

months they produced considerably more than the cows not fed grain—enough more to more than pay for the grain fed.”

Notes are given on the nature of the pasture used in the experiments, on the management of cows on pasture in relation to bloat, and on the relative effects of soiling and pasturing on lucern and mixed grasses.

The composition of human milk, BACKHAUS and W. CRONHEIM (*Ber. Landw. Inst. Univ. Königsberg*, 5 (1900), pp. 61-73).—Analyses of 12 samples are reported, made in connection with an investigation of the best method of modifying milk for infants' use. The results are compared with those of Camerer and Söldner. In agreement with these investigators it was found that there was a discrepancy between the total solids and the sum of the constituents of the total solids as determined separately, amounting to from 0.68 to 2.045 per cent. This is held to represent an unknown constituent which passes into the filtrate when the albuminoids are precipitated with alcohol. Various attempts were made to determine the character of this substance, and the means of isolating it.

Two complete ash analyses of human milk are given. These showed 14.79 and 11.75 per cent of phosphoric acid, 17.36 and 15.52 per cent of calcium oxid, and 33.74 and 27.33 per cent of potassium oxid, respectively. These data are said to be higher in potash and lower in phosphoric acid and calcium oxid than the generally accepted average, for the ash of cows' milk which has been used in making modified milk.

On the composition of Danish butter, H. FABER (*Analyst*, 25 (1900), Aug., pp. 199-201).—Data obtained in connection with the butter shows in Copenhagen are given for 12,000 samples of milk during 9 years. “The average is about 14 per cent [of water], most samples having from 13 to 15 and very few less than 12 per cent or more than 16 per cent.” Analyses of Danish butter imported into England during 1898 and 1899 are given by months, the Reichert-Wollny figure, index of refraction, and Beechi test being reported.

“In Denmark cows are generally housed from the middle of October to the middle of May, and the calving takes place in autumn and winter. Correspondingly, we find the Reichert-Wollny figure higher in the winter and spring than in summer, and lowest in the autumn, the maxima (32.6 and 32.5) for the 2 years occurring in March, the minima (24.3 and 25.6) in October. The effect of moving the cows from cold fields to warm byres in October, additional to the increased number of of new-calved cows, finds its expression in a rapid rise in the Reichert-Wollny figure from October to November.”

The effect of food and of the individuality of the cow on the taste of milk and its tolerance, BACKHAUS (*Ber. Landw. Inst. Univ. Königsberg*, 5 (1900), pp. 110-126).—Cows were given a number of different sorts of coloring matters, condiments, lactic and butyric acids, etc., and the effect noticed upon the color and taste of the milk

and the manner in which it agreed with people. A number of feeding stuffs were also tested. In no case was the taste or the tolerance of the milk affected by feeding large quantities of caraway, fennel, anise, gentian, onion, lactic acid, or butyric acid. Methyl violet was transmitted from the food to the milk, but most other coloring matters gave negative results. An undesirable taste in the milk of some cows was not corrected by changing the food or giving large quantities of ground oats. No disturbances in the agreement of the milk with the children receiving it could be attributed to changes in the food, and none of the feeding stuffs used, including cotton-seed meal, palm-nut cake, and sesame cake, imparted any taste to the milk; neither did these make any material change in the fat content of the milk. The milk of individual cows was found to differ considerably in taste and in the way in which it agreed with children. The milk of some cows was considerably off flavor, the reason for this being attributed to special chemical properties of the constituents and the presence of unorganized ferments. In practice it is recommended to use the milk as quickly as practicable and to employ mixed milk from a large number of animals in order to diminish as far as possible any objectionable quality.

The production of aseptic milk, BACKHAUS and O. APPEL (*Ber. Landw. Inst. Univ. Königsberg*, 5 (1900), pp. 73-102).—This was largely a bacteriological study of the organisms in milk produced under various conditions. It was found possible, by the observance of every precaution in the care of stables and handling of the cows and the milk, to produce milk of relatively low germ content. A number of factors which influence this are noted. The germ content was found to be much larger in summer than in winter. Bacteria multiplied more rapidly in wooden buckets than in tin cans, but in the case of new buckets tannin was believed to check the action after a time. The germ content was not increased by feeding green fodder. Better results were obtained with hand milking than with the use of milking tubes, the latter giving a higher germ content at 4 different stages of the milking. A considerable number of trials with fractional milking showed the germ content to decrease regularly as the milking progressed, and in a few cases the last portion was sterile. The former recommendation to separate the first quarter from the last three-quarters is confirmed. As the result of fractional milkings the authors conclude that the milk in the udder of healthy cows is sterile. Sterile milk and water introduced into the udder suffered no change, and it is believed that the conditions within the udder are unfavorable to the life of the germs most commonly found in milk.

The Cambridge Sentinel milk sterilizer (*Jour. Expt. Med.*, 4 (1899), No. 2, p. 217; *abs. in Nature*, 63 (1900), No. 1624, p. 166).—This is a simple sterilizer made for domestic use. In one form a bell

rings automatically when a temperature of 85° C. is reached; in another the gas is turned off at that temperature. The automatic mechanism is actuated by the melting of an easily fusible alloy. Tests of the apparatus indicated that there was considerable difference in the temperature at which the automatic apparatus worked, due to the amount of liquid in the sterilizer. With a small quantity the bell or cut-off did not work until a temperature of over 95° was reached. The criticism is made that a temperature of 85° is higher than is necessary, 65 to 68° C. continued for 20 minutes being sufficient.

Handling the dairy cow, C. F. CURTISS (*Chicago Dairy Produce*, 7 (1901), No. 65, pp. 30, 31).—Address on feeding and breeding before the Iowa State Dairy Association.

Bibliography of milk, H. DE ROTHSCILD (*Bibliographia lactaria*. Paris: Octave Doyn, 1901, p. 584).—This is a general bibliography of the subject of milk up to the close of 1899, with an introduction by E. Duclaux. It is the most extensive bibliography of the subject ever prepared, including 8,375 titles and dating back to the beginning of the sixteenth century. The titles are arranged by subjects, with entries in chronological order under each subject. An author index and a list of inventions and patents are also given. The subjects covered are the production, composition and properties, handling, bacteriology, adulteration, and utilization of milk as food. Butter and cheese are not included, but koumiss and kephir and condensed and modified milk are included.

The acidity of milk, P. VEITH and M. SIEGFELD (*Milch Ztg.*, 29 (1900), No. 38, pp. 593-597).—From many investigations the conclusion is reached that the natural acidity of milk does not approach a fixed amount, but may show a wide variation. Evening's milk averaged a slightly higher acidity than morning's milk. The variations in acidity were not particularly marked during different portions of the year, but depend more upon the conditions of milking and handling.

Individual variations in milk secretion and the return for food eaten, BACKHAUS (*Ber. Landw. Inst. Univ. Königsberg*, 5 (1900), pp. 103-109).—This is an individual record for 10 cows. The relation of the milk production to the food units consumed and to the cost of food is brought out. The results show wide differences between cows in these respects and indicate very strongly the importance of testing cows, as previously advocated by the author.

Some experiments on the production of acetic acid in milk by lactic-acid bacteria, C. BARTHEL (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 13, pp. 417-420).—Experiments were made with skim milk inoculated with pure cultures of lactic acid bacteria, the flasks containing the milk being in some cases charged with carbonic acid and then sealed, and in others having a current of oxygen conducted through them. Acetic acid was produced under both conditions, although the amount was much larger in the presence of oxygen. The conditions most favorable to the production of acetic acid were found to be those which are known to be most favorable for the growth of lactic-acid bacteria.

Milk inspection, PETERS-HILTNER (*Chicago: Alex. Eger*, 1901, pp. 96).—A manual adapted to the needs of commercial analysts, market inspectors, and health officers. Methods of analysis are given and a bibliography appended.

Rennet action and rennet testing, P. VEITH and M. SIEGFELD (*Milch Ztg.*, 29 (1900), Nos. 42, pp. 657-659; 43, pp. 673-675).—Experiments are reported on the effect of acidity, and of soluble lime salts on the action of rennet and on the means of determining the strength of rennet. At present the only means is said to be an actual trial with milk.

Some lactic-acid bacteria found in ripe cheese, G. LEICHMANN and S. VON BAZAREWSKI (*Centbl. Bakt. u. Par., 2. Abt., 6 (1900), Nos. 8, pp. 245-253; 9, pp. 281-285; 10, pp. 314-331*).—In a study of the flora of ripe Emmenthaler, Chester, and Gouda cheese the authors isolated 5 forms which they designate provisionally as *Bacterium casei* I, II, III, and IV, and *Streptococcus casei*. The characteristics of these different forms and their behavior under a variety of conditions are described in detail.

VETERINARY SCIENCE AND PRACTICE.

Charbon, W. H. DALRYMPLE (*Louisiana Stas. Bul. 60, 2. ser., pp. 341-370*).—During the summer seasons of 1898 and 1899 anthrax prevailed in an epizootic form throughout the State. This disease has acquired an increased economic importance in the State on account of the recent extensive importation of valuable beef cattle. The author believes that the only method by which anthrax can be controlled or eradicated is by the combined effort of stockmen in the State, supported by a rigidly enforced law. The bulletin contains a copy of the British anthrax order which is considered by the author a good basis for a law against anthrax in Louisiana.

Detailed notes are given on a trip of inspection made through the State for the purpose of determining the extent of anthrax, the conditions under which infection takes place, and the sanitary measures adopted. In general it was found that the carcasses of animals which had died of anthrax were either not destroyed, or if so only after a considerable period had elapsed during which contagion might have been spread by flies and carnivorous animals. The author believes that the most important factors in the spread of anthrax in the State are the neglect to destroy diseased carcasses and the prevalence of horseflies. It is recommended that kerosene be spread upon the surface of pools visited by horseflies in order to destroy these insects. A few outbreaks of anthrax were apparently due to eating infected feeding stuffs, such as elevator feed and rice bran. Such contamination of feed is to be considered accidental and has no connection with any particular feeding stuff. The author states that gratifying results have followed the use of preventive vaccination where this method has been employed in the State.

Bacteriological work, F. D. CHESTER (*Delaware Sta. Rpt. 1899, pp. 30-33*).—The author gives a brief report on culture tests for anthrax in 4 suspected cases. A quantity of hog-cholera serum received from a pharmaceutical firm was used in laboratory experiments on guinea pigs. In order to determine the virulence of the culture of hog cholera, 5 guinea pigs were inoculated with varying quantities of a culture in neutral bouillon, with the result that the animals died in from 7 to 19 days. In another experiment 4 guinea pigs were inoculated each with 0.1 cc. of the culture and on the following day

3 of the animals received quantities of hog-cholera serum varying from 0.3 to 1 cc. The 3 animals treated with hog-cholera serum died in from 6 to 7 days. It was apparent from the experiment that this serum was too weak to be of value in the treatment of hog cholera.

Brief notes are added on bacteriology and post-mortem examinations of hogs in outbreaks of hog cholera.

Pleuro-pneumonia in dairy herds, M. A. O'CALLAGHAN (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 627-631).—Pleuropneumonia is said to break out occasionally on a small scale among the dairy herds and other cattle of Australia. The author recommends that in all cases where any outbreak of the disease is suspected, the owner of the animals should take the temperatures of his whole herd twice a day. Any animals which show a temperature above 103° should be isolated at once from the herd in order to prevent the spread of the disease.

A method of preventive inoculation which is in common practice among stock raisers is to saturate cotton threads with the serous fluid taken from the pleuro cavity of diseased animals and to draw these threads under the skin near the end of the tail. The virus upon the threads has the effect of producing a mild form of the disease, which confers immunity against the fatal form.

The stomach worm (*Strongylus contortus*) in lambs, A. G. HOPKINS (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 5, pp. 277, 278).—This parasitic worm was found to be the cause of rapid emaciation, loss of weight, dullness, coughing, and other symptoms of disease in lambs. In the treatment of this disease tonics were administered with practically no results. The lambs were then divided into 2 lots. Lot 1 was given benzine in doses of 2 drams in 2 oz. of milk on 3 successive mornings, while lot 2 was given creolin in doses of 1 dram in 2 oz. of milk for the same length of time. This treatment was applied during fasting of the lambs. Previous to the treatment the lambs were losing weight. When weighed 10 days after the experiment, gains of from 2 to 5 lbs. were noted, which gains were also recorded at subsequent weighings which took place every 2 weeks. The medicines were administered as a drench.

Gruber's reaction in hog cholera, R. R. DINWIDDIE (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 9, pp. 528-532).—The observations recorded in this paper were confined chiefly to experimental animals, including rabbits, pigs, and guinea pigs. Nearly all tests were made with dried blood. Dilutions were made with sterile normal salt solution in the proportion of 1:10, 1:20, and 1:40. When only one slide was prepared for diagnostic purposes a dilution of 1:20 was found most reliable within the limits of half an hour. The blood of 26 rabbits with a dilution of 1:10 was tested with the result that no reaction was obtained in 22 cases. In the other 4 rabbits apparent

reactions were obtained which were not considered typical. No reaction was obtained with normal blood from 12 guinea pigs which were tested, and similar results were obtained from testing the normal blood of hogs. After inoculation with the hog-cholera bacillus the agglutinating property appears in the blood within from 4 to 6 days in rabbits, guinea pigs, pigs, and cattle. When inoculations are made with cultures of feeble virulence, the appearance of the agglutinating property in the blood is frequently delayed several days beyond the usual time. In animals which survived the inoculation the persistence of the agglutinating reaction seemed to depend upon the severity of the disease.

Rabies (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 25, pp. 29*).—This bulletin contains a report of the Committee on Public Health of the Medical Society of the District of Columbia upon the general subject of rabies, with special reference to local conditions. The Medical Society of the District of Columbia, at a meeting held April 11, 1900, referred an investigation of the matter to the Committee on Public Health to recommend such action as might be considered advisable.

The main body of the report is controversial in nature, in which the position is taken that rabies is an acute specific disease due to a specific virus, and is produced ordinarily by the bite or saliva of an infected animal. It is stated that the Bureau of Animal Industry demonstrated by biological test in the District of Columbia 2 cases in 1895, 5 in 1896, 3 in 1897, 7 in 1898, 19 in 1899, and 15 up to the end of March, 1900. The committee gives a general discussion of the symptoms, period of incubation, diagnosis, rate of mortality, treatment, and methods of prevention of rabies. These subjects are further discussed in appendixes to the bulletin, and also the subject of the muzzle as a means of prevention.

An organism pathogenic to rats, J. DANYSZ (*Ann. Inst. Pasteur, 14 (1900), No. 4, pp. 193-201*).—A cocco bacillus which resembles *Bacillus coli* was isolated from an epidemic of field mice and was found to be slightly pathogenic to rats. A number of experiments conducted in feeding cultures of this bacillus to rats indicated that 2 or 3 out of every 10 rats thus fed ultimately died with a disease similar to that produced in mice by the same bacillus. It was found upon further experimentation that this bacillus became gradually weakened in its virulence in passing from rat to rat. Experimental passages of the bacillus through a series of rats demonstrated this fact, as well as the gradually decreasing mortality in the number of rats exposed to infection from this disease. From these results it was believed that the reason for the gradual diminution in virulence of the bacillus was to be found in the regular alternation of media from the intestine to the blood. The bacillus was carefully cultivated on a bouillon medium,

with the result that the virulence was considerably increased for rats. A number of cultures of increased virulence were then distributed in different cities, and experiments conducted in the destruction of rats. The results indicate that this organism furnishes an effective means for ridding cities of rats, but in no case can be relied upon to utterly exterminate the rats in any locality.

The prophylaxis of paludism (*Rev. Sci. [Paris]*, 4. ser., 14 (1900), No. 7, pp. 208-211).—Brief notes on the biology of mosquito larvæ and a discussion of the methods for their destruction.

The propagation of the filariæ of the blood exclusively by means of the puncture of peculiar mosquitoes, B. GRASSI and G. NOË (*British Med. Jour.*, 1900, No. 2079, pp. 1306, 1307).—Experiments by the authors demonstrated that the larvæ of filaria are found in *Anopheles clariger*. The larvæ of filaria sucked up with blood by the mosquitoes migrate into the Malpighian tubes, where they continue their development. At the completion of the larval development the larvæ pass into the body cavity, move forward toward the head, and collect in the prolongation of the body cavity within the labium. Experiments on dogs showed that when *Anopheles* bites these animals the larvæ pass out of the labium and are thus inoculated into the bitten animal.

The communicable diseases of domestic animals that materially affect the live-stock industry, W. C. RAYEN (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 3, pp. 134-139).—Notes on tuberculosis, Texas fever, blackleg, and hog cholera.

The significance of atmospheric infection in the more important animal diseases and means for controlling the danger of such infection, K. KASSELMANN (*Ztschr. Tiermed.*, 4 (1900), Nos. 2-3, pp. 124-142; 4, pp. 260-282; 5, pp. 321-343).—An elaborate critical discussion of the literature of the subject with special reference to tuberculosis, glanders, anthrax, blackleg, rinderpest, sheep pox, contagious pleuropneumonia of cattle, influenza, swine plague, pneumonia of horses, and foot-and-mouth disease. In the general discussion of methods for preventing infection of domesticated animals through the air, the author classifies such measures into 3 groups: Those which tend to prevent the inhalation of micro-organisms in the air, those which prevent the entrance of micro-organisms into the atmosphere, and those which are concerned with destroying micro-organisms in the air. A bibliography of 80 titles is appended.

Colloidal silver, M. KLIMMER (*Ztschr. Tiermed.*, 4 (1900), No. 4, pp. 289-300).—From experiments with this substance in veterinary practice, the author concludes that colloidal silver is best administered with the addition of albumen, gelatin, or gum arabic, in order to protect it from the action of the salts which are found in animal fluids. Colloidal silver injected hypodermically in a physiological salt solution containing albumen is almost completely absorbed. When injected intravenously or hypodermically, it is for the most part excreted in feces. Colloidal silver injected intravenously produces an elevation of temperature in healthy and diseased horses. In the intestines it has only a very slight antiseptic effect.

The value of iodine-protein compounds in veterinary practice, RÜDER (*Arch. Wiss. u. Prakt. Thierh.*, 26 (1900), No. 4-5, pp. 325-335).—The author experimented with several forms of iodine-protein compounds in the treatment of diseases of animals. The results indicate that iodine has the same therapeutic effect when given in combination with protein, but does not have the harmful secondary effects which are noted when it is given alone. The author recommends iodine combined with protein for the treatment of actinomycosis.

Gangrenous sloughing of the tail of domestic animals, ELLINGER (*Berlin. Tierarztl. Wchenschr.*, 1900, No. 43, pp. 505-507).—Various names have been given to

this disease, which consists in the death and falling off of the tip of the tail and sometimes the whole tail. It has been observed especially in cows and young pigs. The cause of the disease is not well understood, but apparently a number of causes might produce this affection of the tail. Among such causes may be mentioned mechanical injuries which result in the interruption of the blood circulation in the tail, the presence of ammonia vapor in unusual quantities, and ergot. The author reviews the literature relating to this subject and describes an outbreak of the disease among pigs in Roumania.

The clinical value of a leucocyte count in the diagnosis of septic infections, G. D. HEAD (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 3, pp. 129-134).—Careful counts of the leucocytes in healthy dogs showed a variation of from 6,600 to 9,600 per cubic millimeter, with an average of about 8,000. The presence of septic infection causes a more or less pronounced leucocytosis. In dogs and rabbits a great increase in the number of leucocytes was noted during septic processes. In one case the number per cubic millimeter rose to 36,300 from a normal average of 9,200. Attention is called to the diagnostic value of a leucocyte count in veterinary practice.

Water hemlock poisoning, E. F. LADD (*North Dakota Sta. Bul.* 44, pp. 563-569, fig. 1).—On account of the unusual dryness of the season, it is reported that animals grazed in low marshy places more extensively than in ordinary years. Water hemlock is frequently found in such localities, and several cases of poisoning have been apparently traced to the action of this plant. In the case of 2 cows good evidence was obtained against water hemlock. An examination of the blood and stomach contents revealed the presence of the active principle of water hemlock.

The article contains a reprint of a previous paper on the same subject (E. S. R., 11, p. 287).

Poisoning from *Glyceria spectabilis* infested with *Ustilago longissima*, J. ERIKSSON (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 1, pp. 15, 16).—About 100 cattle fed with this grass developed symptoms of poisoning within 1½ hours after feeding. Nearly all of the animals recovered after about 3 hours. In another locality 3 cows ate a quantity of this grass and were affected so severely that the owner slaughtered them. The grass in both cases was badly smutted.

Treatment of tuberculosis by muscle plasma or zomotherapy, J. HÉRICOURT and C. RICHET (*Rev. Sci. [Paris]*, 4. ser., 13 (1900), No. 10, pp. 306-308).—The authors conducted experiments upon 16 dogs with 18 other dogs as checks. The experiments showed that cooked meat did not have the same effect as raw meat upon tuberculous animals. The dogs were fed upon raw meat, and in nearly every case resisted the progress of the disease to a greater extent than did the checks, and in many cases final recovery took place.

Treatment of infectious diarrhoea of calves with tannoform, SCHÜMMHOFF (*Berlin. Tierarztl. Wchnschr.*, 1900, No. 14, pp. 161, 162).—Immediately after the birth of calves the author gave 0.05 gm. calomel mixed with sugar, and 15 minutes later 4 gm. tannoform mixed with sirup and meal. These doses were given 3 times on the first day, twice on the second day, and once on the third day. Fairly satisfactory results were obtained in checking the disease.

A review of contagious abortion, S. P. SMITH (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 3, pp. 151-155).—Brief historical notes on the development of the knowledge concerning this disease.

Schmidt's treatment of parturient paresis, A. G. ALVERSON (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 3, pp. 168, 169).—The author gives short notes on 6 cases in which he administered potassium iodid infusions with success in only one case.

Parturient paresis, A. H. HARTWIG (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 3, pp. 142-145).—The author reports results of applying the Schmidt method in the treatment of this disease. Detailed notes are given on 6 cases in which potassium iodid infusions were injected into the udder with recovery in 5 cases. In one case

which developed 8 weeks after calving and in which there were symptoms of mammitis, potassium iodid infusions were not given. The udder was subjected to friction, was frequently immersed in hot water, and was relieved of its contents as often as possible. The cow recovered.

Parturient apoplexy and its treatment, WITT (*Berlin. Tierarztl. Wchnschr.* (1900), No. 22, pp. 253, 254).—The author treated 57 cases of this disease by means of infusions of potassium iodid with recovery in 50 cases after from 6 to 12 hours. The author takes issue with Schmidt in his theory of the nature of the disease and the effect of the potassium iodid treatment. The author noted a relatively lax and soft condition of the udder in 80 per cent of the cows which were treated and a complete or nearly complete cessation of milk secretion in every case. It is believed, therefore, that the cerebral anemia observed in many cases of parturient apoplexy is not due to any increased blood pressure in the udder. The action of potassium iodid infusion has been explained as checking the secretion of milk. The author maintains, on the contrary, that whenever milk secretion is partly checked soon after calving parturient apoplexy is likely to be developed, and that the treatment of the disease consists in stimulating the udder to its customary secretory activity. The author believes that in ordinary cases recovery takes place very rapidly after milk secretion is resumed.

Is a post-mortem examination necessary in the diagnosis of anthrax, STEINBACH (*Berlin. Tierarztl. Wchnschr.*, 1900, No. 41, pp. 481, 482).—According to the author's experience, a post-mortem examination is necessary in suspected cases of anthrax in which a microscopic examination of the blood failed to give a positive diagnosis.

Dehorning (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 7, pp. 387-390).—A brief account of this operation, taken in part from the *Sydney Telegraph*.

Three important diseases affecting sheep, J. D. STEWART (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 837-846).—Notes on stomach worms, lung worms, fluke worms, and foot rot. The author recommends the most approved remedies for the treatment of each of these diseases.

Etiology of louping ill, J. MCFADYEAN (*Jour. Comp. Path. and Ther.*, 13 (1900), No. 2, pp. 145-154).—The author gives a general historical account of this disease. The name louping ill has apparently been applied to a number of distinct diseases, such as pyæmic spinal meningitis, gastritis, enteritis, and disorders of brain functions. The relationship of grass ticks to louping ill is believed by the author to be a problematical question. The author concludes that the etiology and pathology of the disease are still obscure and that the whole subject needs a careful investigation.

Periodical ophthalmia of the horse, L. BERNHARD (*Berlin. Tierarztl. Wchnschr.*, 1900, No. 26, pp. 301-304).—Detailed notes on the symptoms of the disease, together with an account of its prevalence.

Malignant œdema in horses, S. v. RATZ (*Monatsh. Prakt. Thierh.*, 11 (1900), No. 9, pp. 411-416).—Detailed reports are given on the clinical symptoms and post-mortem findings of 2 cases of this disease in horses. The bacilli were strikingly similar to those of blackleg. White mice inoculated with œdematous material died 2 days later.

The pathogenic organism of horse sickness, RICKMANN (*Berlin. Tierarztl. Wchnschr.*, 1900, No. 27, pp. 314-316, fig. 1).—It was found by experiment that if virulent blood from a case of this disease was passed through a Chamberlain filter it ceased to be virulent. A microscopic examination of such blood revealed the presence of micro-organisms similar to those of malaria.

The horses of South Africa and their most important diseases, especially malaria, ZERN (*Ztschr. Tiermed.*, 4 (1900), No. 2-3, pp. 143-163).—The author gives a description of the tsetse fly (*Glossina morsitans*) and discusses its agency in the transmission of malaria to horses. A number of species of flies of the same genus

are found in South Africa and many of them have been suspected of carrying malaria. The author offers a critical review of the literature of this subject. Notes are also given on anthrax and strangles. Detailed directions are given for the application of the most important methods for destroying mosquitoes and the tsetse fly and for keeping these insects out of stalls and stables.

Chronic tuberculosis in the horse, M. SCHWAMMEL (*Ztschr. Tiermed.*, 4 (1900), No. 2-3, pp. 182-186).—The author reviews briefly the literature on tuberculosis in the horse. Detailed notes are given on a post-mortem examination of a case of chronic tuberculosis in the horse. In general the post-mortem appearances were similar to those of bovine tuberculosis. The disease was readily distinguishable from glanders by the fact that the characteristic lesions of glanders were absent. The horse had been kept on an estate where from 60 to 80 per cent of cattle were infected with tuberculosis. Some of the cattle were draft oxen and had been allowed to stand temporarily in the same stall where the horse was kept. It is believed that the disease was transmitted in this manner.

The hyphomycetous nature of the glanders bacillus, H. CONRADI (*Ztschr. Hyg. u. Infektionskrankh.*, 33 (1900), No. 2, pp. 161-177, pls. 2).—The author gives a review of the literature on the subject of the morphological structure of the glanders bacillus. From a bacteriological study of the organism of glanders, the author believes that it does not belong properly to the bacteria, since it was shown that the normal developmental processes of the organism lead to stages which show a monopodial branching and false branching similar to that of *Cladothrix*. The organism of glanders is believed by the author to be closely related to the *Actinomyces* group fungi.

Pathological-anatomical studies of the Borna disease, H. DEXLER (*Ztschr. Tiermed.*, 4 (1900), No. 2-3, pp. 110-121, figs. 3).—An examination of the cervical region of the spinal cord in cases of this disease disclosed the presence of a recent inflammation of the membranes which had progressed for some distance into the substance of the brain and spinal cord. From a careful study of cases of the Borna disease, the author considers as diagnostic certain structural changes in the central nervous system, especially in the substance of the cervical region of the spinal cord, the pia mater of the hemispheres, the lateral plexus of the cerebellum and in the cortex of the cerebrum. The author concludes that the Borna disease should be characterized as a meningo-encephalitis and myelitis.

The etiology of rabies, S. v. RATZ (*Monatsh. Prakt. Thierh.*, 11 (1900), No. 9, pp. 402-410).—The author gives a critical review of the literature relating to the possible hereditary transmission of rabies. From the brain of a pregnant cow which had died of rabies, material was taken for the inoculation of rabies with the result that the characteristic symptoms of rabies were produced in the experimental animals. Material taken from the fetal brain failed to produce rabies in rabbits. The author made a number of experiments in inoculating animals with material from the brain of dogs which had died of rabies. The dogs were allowed to remain buried for varying periods before the material was taken from the brain for inoculation. The results of these experiments indicate that the virus of rabies is present in the brain of dogs which have been buried from 14 to 24 days. Putrefaction, however, had the effect of weakening the virulence.

Experiments on the action of Epicarin in the treatment of mange of dogs, REGENBOGEN (*Monatsh. Prakt. Thierh.*, 11 (1900), No. 4, pp. 145-149).—Experiments made by the author for the purpose of determining the value of epicarin in the treatment of dog mange gave the following results: Epicarin given internally in 0.5 gm. per kilogram of body weight is not poisonous. Isolated *Sarcoptes squamiferus* and *Acarus folliculorum* were killed much less quickly by alcoholic solutions of epicarin than by solutions of cresol preparations. The treatment of mangy dogs was not satisfactory, since considerable time and trouble were involved in the application of the method and the results were uncertain.

TECHNOLOGY.

Preservation of unfermented grape must, F. T. BIOLETTI and A. M. DAL PIAZ (*California Sta. Bul.* 130, pp. 12, figs. 4).—The composition of pure grape must and of the products sometimes found on the market is discussed, as well as the causes of spoiling of grape juice and the chemical and physical means of preventing fermentation. Chemical methods, *i. e.*, the use of germ poisons or antiseptics, are condemned. The physical methods, especially those depending upon the application of a temperature sufficiently high to kill all germs, are considered safest and most reliable. Such a method is described in some detail. It is recommended that only clean and perfectly sound grapes, picked and handled when cool, should be used. After the juice is expressed it is allowed to settle 24 hours and then run through a continuous pasteurizer in which it is heated to 80° C. (176° F.), but comes out not warmer than 25° C. (77° F.). It is again allowed to settle in closed sterilized casks and filtered. For this purpose a filter so constructed that the must passes upward through the filtering medium under pressure is recommended. The filtered juice is placed in bottles previously sterilized, and the stoppered bottles are kept in a water bath heated to 85° C. (185° F.) for 15 minutes (for quart champagne bottles). By this means the contents of the bottles are heated to about 75° C. (167° F.). If a higher temperature is used for the second sterilization than for the first the must becomes cloudy. To prevent the growth of mold on the corks in storage they may be dipped in hot paraffin or 2 per cent bluestone solution.

Utilization of pure yeasts in wine fermentation, R. CHODAT (*Arch. Sci. Phys. et Nat.*, 8 (1899), pp. 588, 589; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 2, pp. 237, 238).—The advantages of the use of pure yeasts in wine fermentation are pointed out and details of an investigation of a red wine of Crete are given. Six species of *Saccharomyces* were isolated from this wine, one of which belonged to the *S. apiculatus* group, the rest being true yeasts. The amount of alcohol produced by these different yeasts in sterile must is given, and the quantity of glucose destroyed in the production of alcohol or in their own maintenance varied from 7 to 84.4 per cent of the amount present.

Keeping cider, SCHELLENBERG (*Jahresber. Vers. Stat. u. Schule, Wädenswil*, 1897-98, pp. 33-36).—Three casks, each containing 600 liters, were filled with pear cider of like quality. After fermentation the cider was left with the dregs in one case, drained off in the second, and filtered through a cellulose filter in the third, after which the cider in all 3 casks was left in a storage cellar. The summer following the cider in the first cask tasted of the dregs and was of poor quality; that in the second was clear and tasted pure. The cider in the third cask was the best in quality of all. It was not only clear and pure tasting, but had also a fresh, lively character. The conclu-

sion is reached that both the keeping quality and character of pear cider is improved by filtration after fermentation.

In another experiment pears, still hard, but which fell easily from the trees, yielded 58 liters of juice per 100 kg. of fruit. Good, ripe, mellow fruit yielded 65 liters per 100 kg. of fruit; while overripe fruit yielded but 57.2 liters per 100 kg. of fruit.

The keeping quality but not the taste of pear cider was improved by the addition of sugar and water to the juice before fermentation.

Wine making in hot climates, L. ROOS, translated by R. DUBOIS and W. P. WILKINSON (*Melbourne: Government, 1900, pp. 273, pls. 4, figs. 59*).—This is one of the publications of the Viticultural Station of the Department of Agriculture of Victoria, Australia, located at Rutherglen.

The use of yeast in making currant wine, W. KELHOFER (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1897-98, pp. 53-57*).—Pure yeast cultures, beer yeast, dry pressed yeast, and no artificial addition of yeast whatever, were used in making currant wine. The chemical composition of the wine produced in each case is tabulated. The conclusion is reached that when pure yeast for wine-making can not be obtained, a good wine for household purposes can be made by the use of fresh beer yeast at the rate of 50 cc. per hectoliter of juice. Next in value would be newly-made dry yeast, using 20 gm. for each hectoliter of juice. The fermentation of berries and juice together resulted in bad-tasting wine which easily spoiled.

Wine making in Russia, M. BALLOS (*St. Petersburg: Department of Agriculture, 1899, pt. 5, pp. XI+455; rev. in Selsk. Khoz. i Lyesov., 196 (1900), Feb., p. 469*).—This volume is devoted to a description of the industry in Southern Russia.

The briar root industry in Italy (*Sci. Amer. Sup., 50 (1900), No. 1292, p. 20718*).—A record of the production of the root of *Erica arborea* for use in making tobacco pipes.

AGRICULTURAL ENGINEERING.

Water resources of Porto Rico, H. M. WILSON (*Water Supply and Irrigation Papers, U. S. Geol. Survey, No. 32, pp. 48, pls. 15, maps 2, figs. 10*).—This is a report based on notes, sketches, and photographs collected by the author "during a brief journey made through the Island of Porto Rico in January, 1899. The object of this trip was primarily to study the topographic characteristics and the water resources of the island, but incidentally numerous memoranda relative to the soil, agricultural products, and forests were obtained."

The following topics are discussed: Topographic relief—coastal topography, and physiography and scenery; climatology—precipitation and temperature; hydrography—irrigation; agricultural lands and soil—old fields and fertilizers, and agricultural products; forestry; water power and supply; and transportation facilities.

On about three-fourths of the area of the island (north side) the rainfall is sufficient for crops.

"The other one-fourth, including all the region near the coast and from Cabo Rojo on the extreme west to beyond Guayama on the east, must be irrigated if the soil is to produce the full measure of crops of which it is capable. The total area of these irrigable lands is, however, relatively small. . . .

"The soil on these lands is in every case of the very best kind for agriculture with irrigation. It is usually an open, porous, limestone soil of sandy and gravelly texture, mixed with a little earthy loam. It is fairly deep and is underlain by a porous limestone or coral, which affords the best drainage and probably renders it safe from the danger of producing alkali. . . .

"While the precipitation is insufficient, the perennial flow of the streams is unusually abundant for a land requiring irrigation. The minimum discharges of these streams where they would be diverted in the foothills are moderate in amount and yet nearly sufficient for the irrigation of such areas as they command. Moreover, the flood discharges of these streams occur at frequent intervals throughout the year, but are especially well distributed throughout the summer or rainy season. They afford an abundant surplus for storage. The shapes of the smaller parting valleys and of the lower canyons through which the rivers emerge from the mountains give every indication that abundant opportunities will be found, on fuller investigation, for the construction of storage reservoirs at moderate expense and at relatively small cost."

Irrigation has been practiced to some extent, especially on sugar cane. The irrigation works which have been constructed correspond in general type with those of Mexico, but are usually of a more substantial character. Temporary distributaries, however, are used to a considerable extent in the irrigation of sugar cane.

"The volume of water available for utilization either as supply for domestic purposes in the various cities or for conversion into power through the agency of water wheels is relatively great. While this is especially true of the north side of the island, it applies also in a measurable degree to the south side."

The soils of the island are primarily of two classes—calcareous and clay. In some localities they have been over cultivated without fertilization and are now abandoned, but as a rule "the soil of Porto Rico is so deep and fertile, the precipitation so abundant and well distributed, and the temperature, though tropic, so mild as to render it possible to cultivate almost all the land on the island."

Supplies of fertilizers—green sand marl, guano, phosphates, etc.—are abundant.

Road making and maintenance, T. AITKEN (*London: Charles Griffin & Co., 1900, pp. XVI+440, pls. 12, figs. 118, dgm. 3*).—"This treatise is divided into two parts. The first relates to the making and the maintaining of macadamized roads, while the second part deals with carriageways and footpaths." There is a preliminary historical sketch of road making and maintenance. Chapters are devoted to the following subjects: Resistance to traction—wheels and weights on them; laying out new roads, and the improvement of existing lines of communication; earthworks, drainage, retaining walls, culverts, bridges, and protection of roads; road materials or metal; quarrying; stone breaking and haulage; road rolling and scarifying; the construction of new, and the maintenance of existing roads; carriageways and footways—preliminary remarks—foundations and pitched pavements; wood pavements; asphalt pavements; brick pavements, tar macadam, and miscellaneous materials used for carriageways—conclusions; footways, curbs, channels, gullies, paving materials for footpaths; and subways. Methods of carrying out the work and the cost of each operation in the systematic making and repairing of roads and streets and the construction and maintenance of carriageways and footways are given in detail, the information being for the most part the result of practical experience extending over a number of years. The methods apply especially to English conditions.

Some preliminary notes on the hygienic value of various street pavements as determined by bacteriological analyses, S. BURRAGE and D. B. LUTEN (*Proc. Indiana Acad. Sci.*, 1899, pp. 61-67, figs. 7).—Examinations of cultures exposed on an ordinary surveyor's tripod over various kinds of pavements are reported. The conclusion is reached from these observations that "if the amount of dust floating over any given pavement is a measure of the sanitary value, the pavements in question will take the following rank: Wood, brick, sheet asphalt, and macadam."

Hydrography of Nicaragua, A. P. DAVIS (*Twentieth Ann. Rpt. U. S. Geol. Survey*, 1898-99, pp. 563-637, pls. 12, figs. 4).—This paper gives the results of observations made during 1898 in connection with the investigations of the Nicaragua Canal Commission. It deals with general topographic features, rainfall, temperature and relative humidity, evaporation, resources and productions, population, the ship transit problem, and investigations by the Nicaragua Canal Commission, 1898.

Report of progress of stream measurements for the calendar year 1898, F. H. NEWELL (*Twentieth Ann. Rpt. U. S. Geol. Survey*, 1898-99, pt. 4, pp. 1-562, pls. 63, figs. 218).—This is a detailed report of measurements which have been published in previous bulletins of the Survey (E. S. R., 11, p. 1094).

Influence of vegetation on the water flow of rivers, E. WOLLNY (*Vrtljschr. Bayer. Landw. Rath.*, 5 (1900), No. 3, pp. 389-445).

Mitigation of floods in the Brisbane River, A. C. GREGORY (*Queensland Geogr. Jour.*, n. ser., 15 (1900), No. 1, pp. 41-54).

Bearing-testing dynamometer, M. J. GOLDEN (*Proc. Indiana Acad. Sci.*, 1899, pp. 83-85, fig. 1).—A machine used by the author to determine the amount of power lost by friction in different forms of shaft bearings is described.

The stave silo, J. H. GRISDALE (*Canada Cent. Expt. Farm Bul.* 35, pp. 11, figs. 8).—Brief directions are given for the construction of a stave silo similar to that described by the New York Cornell Station (E. S. R., 11, p. 294), and of a cheap rectangular silo, with notes on crops for silage and methods of filling a silo.

A mechanical cotton picker (*Sci. Amer.*, 82 (1900), No. 21, p. 330, fig. 1).—Brief technical description.

STATISTICS—MISCELLANEOUS.

Eleventh Annual Report of Delaware Station, 1899 (*Delaware Sta. Rpt.* 1899, pp. 201).—This includes a financial statement for the fiscal year ended June 30, 1899, the organization list of the station, summarized and detailed reports of the work of the different departments during the year, a number of articles abstracted elsewhere, and reprints of Bulletins 42, 44-46 of the station on the following subjects: The European and Japanese chestnuts in the eastern United States (E. S. R., 10, p. 962), sorghum in 1899 (E. S. R., 11, p. 141), the root pruning of young fruit trees (E. S. R., 11, p. 845), the southern or cowpea in Delaware (E. S. R., 12, p. 435), dairy value of pea-vine silage compared with that of June pasture (E. S. R., 12, p. 481).

Thirteenth Annual Report of New York Cornell Station, 1900 (*New York Cornell Rpt.* 1900, pp. XL+562).—The report proper includes the organization list of the station and brief reports on the work and expenditures of the station by the director, treasurer, and heads of departments. The report of the assistant professor of dairy husbandry and animal industry gives in addition a statement of conditions governing butter tests of thoroughbred cows made by the station and directions for station representatives in conducting official tests of dairy cows. Appendix I contains reprints of Bulletins 171-182 of the station on the following subjects: Concerning patents on gravity or dilution separators (E. S. R., 11, p. 389), the cherry fruit fly—a new cherry pest (E. S. R., 11, p. 866), the relation of food to milk fat (E. S. R., 11, p. 1081), the problem of impoverished lands (E. S. R., 11, p. 1022), fourth report on Japanese plums (E. S. R., 11, p. 1045), the peach-tree borer (E. S. R., 12, p. 63), spraying notes (E. S. R., 12, p. 163), the invasion of the udder by bacteria

(E. S. R., 12, p. 184), introduction to field experiments with fertilizers (E. S. R., 12, p. 125), the prevention of peach-leaf curl (E. S. R., 12, p. 259), pollination in orchards (E. S. R., 12, p. 237), and sugar-beet investigations for 1899 (E. S. R., 12, p. 335). Appendix II contains a detailed statement of receipts and expenditures of the station for the fiscal year ended June 30, 1899. Appendix III contains reprints of publications on nature study.

Twelfth Annual Report of Rhode Island Station, 1899 (*Rhode Island Sta. Rpt. 1899*, pp. IX + 227).—The report of the director gives a general review of the work of the station during the year and departmental reports review in detail the different lines of work and contain a number of articles noted elsewhere. A financial statement for the fiscal year ended June 30, 1899; lists of donations, exchanges, and station publications; and an index to the report and Bulletins 52-55 of the station issued during the year, are included.

Experiment Station Work—XV (*U. S. Dept. Agr., Farmers' Bul. 119*, pp. 31, figs. 5).—This number contains articles on the following subjects: Storing apples without ice, cold storage on the farm, mechanical cold storage for fruit, keeping qualities of apples, improvement of blueberries, transplanting muskmelons, banana flour, fresh and canned tomatoes, purslane, mutton sheep, effect of cotton-seed meal on the quality of butter, grain feed of milch cows, and protection against Texas fever.

Timely hints for farmers (*Arizona Sta. Bul. 34*, pp. 65-115, figs. 14).—This bulletin is a collection of popular articles issued by the experiment station from October 1, 1899, to June 15, 1900. The following subjects are discussed: Green manuring plants for orchards, planting eucalypts in Arizona, improvement of Arizona soils, winter irrigation of orchards, the crown gall, desirable varieties of peaches, the danger of introducing insects on trees, what to plant on arbor day, winter remedies for injurious insects, care of milk for the factory, black alkali, white alkali, selecting dairy cows, the adobe hole, dehorning cattle, date palm culture, summer cultivation, and grazing *v.* irrigation.

Agricultural exports of the United States by countries, 1895-1899, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 20*, p. 88).—Statistical tables are given showing the character and value of the agricultural products exported from the United States to each country of destination during the 5 fiscal years 1895 to 1899. The average annual value of the agricultural exports during the 5 years was \$694,874,000. The United Kingdom received 53.37, Germany 13.60, and France 6.22 per cent of the total exports. Of the products exported cotton, breadstuffs, and meat products amounted respectively to 30.71, 30.56, and 20.36 per cent.

Agricultural imports of the United States by countries, 1895-1899, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 21*, pp. 74).—Statistical tables are given showing the character and value of the agricultural products imported into the United States from each country of shipment during the 5 fiscal years 1895 to 1899. The average annual value of the agricultural imports during the 5 years was \$366,964,708. Brazil supplied 14.75, the United Kingdom 9.30, Cuba 7.47, and Germany 6.57 per cent of the total imports. Of the products imported, sugar amounted to 22.90 per cent, and coffee, 20.86 per cent.

The production and consumption of corn in United States, Hungary, Roumania, and other countries, E. RABATE (*Jour. Agr. Prat.*, 1900, II, No. 46, pp. 721-725).—Statistics and discussion.

List of free employment agencies for the use of farmers (*U. S. Dept. Agr., Division of Statistics Circ. 13*, pp. 42).—"A list of free employment agencies, and other institutions and individuals willing to act as such, which are likely to be able to supply farm laborers, domestic servants, or other employees for permanent or temporary employment in the country." The list includes nearly 1,000 names arranged by counties in the different States.

NOTES.

TENNESSEE STATION.—The executive committee of the station has been reorganized with J. W. Caldwell, of Knoxville, as chairman, and J. B. Killebrew, of Nashville, and Harris Brown, of Gallatin, as additional members. At the semiannual meeting of the board of trustees Andrew M. Soule was elected vice-director of the station, in addition to his duties as professor of agriculture and agriculturist. The vice-director will henceforth supervise the work and business of the station under the direction of the president. There are 35 students attending the dairy school, and a keen interest and appreciation of the work the station and college of agriculture are doing is evidenced on every hand. The agricultural yearbook for 1891 was recently issued, and has proved very popular among the farmers all over the South. In fact, the demand for publications has become so great that with the limited resources at the command of the station it is becoming a difficult problem to meet the call for station literature.

FIFTH INTERNATIONAL CONGRESS OF ZOOLOGY.—The preliminary announcement of the Fifth International Congress of Zoology, to be held at Berlin, August 12–16, has been received. In addition to the regular sessions of the congress and of sections, various excursions are planned to zoological museums, gardens, institutes and other institutions likely to be of interest to zoologists, a reception, and a banquet. The formal meetings of the congress will conclude Friday noon, and in the afternoon the delegates will proceed to Hamburg, visiting the national-history museum and the zoological gardens, and on Sunday (August 18) an excursion to Heligoland to visit the biological station there is planned. Anyone interested in zoology may become a member of the congress on payment of \$5, which will insure a report of the congress. All correspondence relating to the congress or to the programme should be addressed to the president of the congress, 43 Invalidenstrasse, Berlin, N. 4.

AGRICULTURAL EXPERIMENTATION AND EDUCATION IN THE WEST INDIES.—At the third agricultural congress, held at Barbados, January 5, Dr. D. Morris, commissioner of agriculture for the West Indies, described the progress which is being made under the Imperial Department of Agriculture in the direction of agricultural experimentation and investigation. "During the year three new experiment stations have been establishment at Montserrat and one at Tortola for the Virgin Islands. At the present time there are 9 botanic stations maintained from imperial funds under the charge of the Imperial Department of Agriculture. In addition, there are 20 substations, or experiment plats, started at Grenada, St. Vincent, St. Lucia, and Dominica to encourage the improved cultivation of cacao, coffee, limes, and other crops. There are 12 central, manurial, and local stations associated with the sugarcane experiments at Barbados, 7 similar stations at Antigua, and 3 at St. Kitts-Nevis. Experimental cultivation with food and other crops will be carried on in connection with all the agricultural schools." During the past year lectures to teachers in charge of elementary schools have been carried on in every part of the West Indies, and the belief is expressed that within a year or two, in the smaller islands at least, every teacher in charge of a school should be qualified, not only to give a certain amount of instruction in the principles of agriculture, but also to interest the children by simple experiments followed by practical demonstrations in the cultivation of plants suited to the district. The first agricultural school in the West Indies affording

secondary education for boys was opened at St. Vincent in September, and a similar school was opened at Dominica in December, 1900. It is planned to establish two more agricultural schools the present year, one at St. Lucia and another, combining the characters of an agricultural school and grammar school, at St. Kitts. Seven scholarships in agriculture at Harrison College, Barbados, have been established by the Imperial Department of Agriculture. Agricultural fairs have been successfully conducted, and have proved of value in stimulating effort toward better production. The Department of Agriculture has encouraged these by prizes amounting to £350 and the distribution of 100 diplomas.

MISCELLANEOUS.—Congress has ordered a reprint of 5,000 copies of Bulletin No. 80 of this Office, the account of the agricultural experiment stations of the United States, prepared for the Paris Exposition. Of this revise the Department of Agriculture is to have 2,000 copies.

Science states that a committee has been appointed by the president of the British board of agriculture to conduct experimental investigations regarding the communicability of glanders under certain conditions, and the arresting and curative powers of mallein when repeatedly administered. The committee consists of A. C. Cope, chief veterinary officer of the board of agriculture; J. McFadyean, principal of the Royal Veterinary College; William Hunting, veterinary inspector; and J. McIntosh McCall, assistant veterinary officer of the board of agriculture.

As a result of correspondence of a committee of the Society of Plant Morphology and Physiology with the editor of the *Botanisches Centralblatt*, urging certain changes in that journal, the editor announces that hereafter the regular series of the *Centralblatt* will be confined to abstracts and reviews of new literature. The original articles will be published in the *Beihefte* or supplements issued from time to time, and the regular series of the *Beihefte* can be subscribed for separately. An American board of editors of the *Centralblatt*, to be selected by the society, is also provided for. It is thought that these changes will make the *Centralblatt* a more valuable medium through which American botanists may keep posted on the progress of their science and the new literature relating to it.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The EDITOR and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. 9.

Editorial notes:	Page.
Cheese curing in the light of the enzym theory.....	801
The agricultural appropriation act.....	803
Russian soil investigations.....	807
Recent work in agricultural science.....	819
Notes.....	899

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

The qualitative detection of mineral phosphates in Thomas slag, N. von Lorenz	819
Estimation of alkali carbonates in the presence of bicarbonates, F. K. Cameron.....	819
Methods of determining proteid nitrogen in vegetable materials, G. S. Fraps and J. A. Bizzell.....	819
A new method for the determination of nitric nitrogen, J. F. Pool.....	820
Estimation of nicotin, amount of nicotin in New South Wales tobaccos, G. Harker	820
The adulteration and analysis of the arsenical insecticides, J. K. Haywood...	820
Composition and analysis of London purple, J. K. Haywood.....	821
Paris green and London purple in Montana, F. W. Traphagen.....	822
Detection of coal-tar dyes in fruit products, A. L. Winton.....	821
The influence of carbon bisulphid and common salt on the losses of nutrients and the character of the fermentation of ensiled fodders, I. Kalugin and S. Parashchuck	822

BOTANY.

	Page.
Some native forage plants of the State, E. V. Wilcox.....	827
Some new species of the genus <i>Cratægus</i> and notes on some dichotomous <i>Panicums</i> , W. W. Ashe	827
Flowers and fruits of common trees and shrubs, F. H. Hillman.....	827
Recent investigations concerning the effect of perchlorates on the growth of crops, P. de Caluwe	824
Electricity in plant culture.....	825
On the embryo of mummy wheat and barley, E. Gain	825
Injuries to plants by London fogs and smoke, G. Henslow	826

ZOOLOGY.

The food of the bobolinks, blackbirds, and grackles, F. E. L. Beal.....	828
Results of the biological reconnaissance of the Yukon River region, W. H. Osgood and L. B. Bishop	830
Information concerning game: Seasons, shipment, and sale, T. S. Palmer and H. W. Olds.....	830
Wild animals and birds which may be imported without permits, J. Wilson ..	830
Laws regulating the transportation and sale of game, T. S. Palmer and H. W. Olds.....	831

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review, Vol. XXVIII, Nos. 7-9	831
Report on the international cloud observations, F. H. Bigelow	831
Climatological atlas of the Russian Empire	834
Amount of chlorin in rain water collected at Cirencester, E. Kinch.....	832
Rain, river, and evaporation observations in New South Wales, 1898, H. C. Russell	833
Summary of weather at the North Louisiana Experiment Station during 1892-1899, J. G. Lee.....	834
Meteorological summary for 1899	834

WATER—SOILS.

Principles of water analysis as applied to New Mexico waters, A. Goss	834
The purification of water, especially the removal of lime and magnesia, K. Schierholz	835
Water supply and sewerage	835
Nitrification and catch crops, P. Bonâme.....	836
New researches into Pouillet's phenomenon (the heat developed in wetting powders), T. Martini	837
Recent observations on the diluvial formation in the Netherlands with special reference to charting, II, H. Van Cappelle	837
On the causes of the treeless conditions of the steppes, S. Kravkov.....	838

FERTILIZERS.

The influence of the distribution of fertilizers on their action, J. M. Pomorski.	839
Field experiments with phosphoric acid in various forms, F. W. Dafert and O. Reitmair.....	839
The action of burnt lime and marl on light sandy upland soils, Neuberth	840
Inspection and analyses of fertilizers, W. F. Hand et al	841
Analyses and valuations of fertilizers, L. A. Voorhees and J. P. Street	840
Another warning in regard to compost peddlers, W. A. Withers.....	841

FIELD CROPS.

	Page.
Field experiments, J. G. Lee.....	841
Report of the agriculturist, E. R. Lloyd.....	849
Report of the assistant agriculturist, R. S. Shaw.....	849
Results of fertilizer experiments with sulphate of ammonia, Kloeppfer.....	843
Fertilizer experiments with Thomas slag and nitrate of soda supplementary to barnyard manure, Lilienthal.....	843
Inoculation of soils, G. W. Herrick.....	843
Researches on the culture of blue lupines, P. P. Dehérain and E. Demoussy..	844
Varieties of cotton, E. R. Lloyd.....	844
Potato improvement and culture, M. Fischer.....	845
Lime experiments with potatoes on light marsh soil, Lilienthal.....	845
Experiments in the culture of the sugar beet in Nebraska, H. H. Nicholson and T. L. Lyon.....	846
Report of wheat raisers, J. Fields.....	850
Experiments with wheat, 1900, F. C. Burtis and J. G. Kerr.....	846
Field experiments with wheat, J. F. Hickman.....	848

HORTICULTURE.

Cabbage—fertilizers, varieties, shipping; cauliflower—varieties and shipping, B. C. Pittuck and S. A. McHenry.....	850
The use of chemical manures on garden vegetables, G. Truffaut and Denaiffe..	851
Report of the horticulturist, S. M. Emery.....	853
Top-working apple trees, G. H. Powell.....	852
Tests of small fruit, J. Troop.....	854
Strawberries, F. S. Earle.....	854
Resistance of strawberries to frost, E. V. Wilcox.....	854
Experiments on the use of nitrate of soda in the culture of grapes, E. Marre..	852
Experiments with manures on vines, E. Zacharewicz.....	852

DISEASES OF PLANTS.

Some field experiments with formalin, M. B. Thomas.....	855
Treatment of seed oats for smut, E. V. Wilcox.....	859
Seed treatment for the prevention of beet diseases, M. Hoffman.....	855
Potato scab, E. V. Wilcox.....	859
The rotting of greenhouse lettuce, G. E. Stone and R. E. Smith.....	856
Orange culture and diseases, J. Borg.....	857
A fig disease, G. Massee.....	858
The sulphuring of grapes, F. Simonet.....	858
Mercury in the products of vines sprayed with mercurial mixtures, L. Vignon and J. Perraud.....	858

ENTOMOLOGY.

Proceedings of the twelfth annual meeting of the Association of Economic Entomologists.....	860
First report on insect pests for 1899, F. V. Theobald.....	862
Report of the botanist and entomologist, G. W. Herrick.....	867
The Hessian fly in 1899 and 1900, F. M. Webster.....	862
The Hessian fly in West Virginia and how to prevent losses from its ravages, A. D. Hopkins.....	863
Losses caused by the grain aphid, E. V. Wilcox.....	868
Experiments with insecticides upon potatoes, C. D. Woods.....	863

	Page.
The economic entomology of the sugar beet, S. A. Forbes and C. A. Hart.....	868
Economic and biological notes on insects injurious to herbaceous crops in the Valley of Bientina, G. del Guercio.....	865
The effect of scale lice upon vegetable tissues, J. Kochs.....	865
Injurious fruit insects; insecticides; insecticide apparatus, R. A. Cooley.....	869
How to control the San José scale, C. L. Marlatt	869
Economic and biological notes on <i>Simathis nemorana</i>	866
Observations on the development and use of the locust fungus in German southwest Africa, Rickmann and Kaesewurm	866

FOODS—ANIMAL PRODUCTION.

Beans, peas, and other legumes as foods, Mary H. Abel.....	876
Studies on the amount of nutrients required by man at rest, K. Elkhholm	871
On the elimination of nitrogen, sulphates, and phosphates, after the ingestion of proteid food, H. C. Sherman and P. B. Hawk.....	871
Digestion trials, J. Fields and A. G. Ford.....	872
Digestion experiments with sheep, J. M. Bartlett	873
A comparison of determined and calculated heats of combustion, L. H. Merrill.	873
Experiments on the influence of asparagin and ammonia upon the metabolism of protein in herbivora, O. Kellner et al.....	874
Inspection of concentrated commercial feeding stuffs during 1900, W. H. Jordan and C. G. Jenter.....	877
Analyses of commercial feeding stuffs, J. L. Hills, C. H. Jones, and B. O. White.	877
Methods of steer feeding, G. C. Watson and M. S. McDowell.....	875
Principles and practices of stock feeding, J. L. Hills.....	877
Feeding experiments, E. R. Lloyd.....	878
Sheep-feeding experiments in Nebraska, E. A. Burnett	875
Roots and other succulent foods for swine, C. S. Plumb.....	876
Live stock; poultry, J. G. Lee	878
Index relating to animal industry, 1837 to 1898, G. F. Thompson	878

DAIRY FARMING—DAIRYING.

Dairy husbandry, J. S. Moore.....	883
Sugar-beet pulp as a food for cows, H. H. Wing and L. Anderson	878
The liability of the total solids of milk to change with age and its effect in the control of market milk, A. Reinsch and H. Lührig	879
Studies of the market milk of Helsingfors, with special reference to its bacteria content, O. von Hellens	879
Preservatives in dairy produce, G. S. Thomson.....	879
Composition of butter made in the Netherlands and conditions which control the changes in composition, J. J. L. Van Rijn.....	880
The influence of certain conditions in churning on the amount of water in butter, J. B. Weems and F. W. Bouska.....	881
The result of working on the water content of butter, J. Siedel and Hesse....	881
The chemical action of molds on butter, J. Hanuš and A. Stocky.....	882
Cream testing, C. H. Eckles.....	882
The source of separator slime, P. Vieth and M. Siegfeld.....	883
A study of butter increasers, J. B. Weems and F. W. Bouska.....	883

VETERINARY SCIENCE AND PRACTICE.

Communications from the official veterinary sanitary reports for the year 1898, J. Esser and W. Schütz.....	884
Texas fever in the Argentine Republic.....	885
Parturient apoplexy under Schmidt's treatment, J. H. Tennent.....	886

	Page.
Report of veterinarian, J. C. Robert.....	890

EXPERIMENT STATION RECORD.

VOL. XII.

No. 9.

The physical and chemical processes involved in the ripening or curing of cheese are extremely complex, and exact knowledge relating to them has been sadly wanting until very recent years. As a cheese matures or becomes fit for consumption not only is there produced the characteristic flavor that is peculiar to the type of cheese made, but with all kinds, regardless of the quality of flavors formed, a profound physical transformation of the casein occurs. In this change the firm elastic curd "breaks down;" *i. e.*, becomes plastic, and, from a chemical point of view, the insoluble casein is converted into various soluble decomposition products.

In discussing these ripening phenomena, the production of flavor and the breaking down of the casein—*i. e.*, the formation of proper texture—have been regarded as different phases of the same process. But, as later shown, these changes are not necessarily so closely correlated.

The theories that have been advanced in the past as explanatory of the ripening changes in cheese have been suggestive rather than founded on experimental data, and it is only within the last five years that carefully controlled scientific studies of this problem have been made.

At the present time two theories have been advanced which purport to account for the changes involved. One of these, which is essentially European, ascribes the ripening changes wholly to the action of living organisms—the bacteria present in the cheese. The other originated in this country, and asserts that there are digestive enzymes inherent in the milk itself that render soluble the casein of the milk.

The adherents of the bacterial theory are divided into two classes. One, led by Duclaux, considers that the breaking down of the casein is due to the action of liquefying bacteria (*Tyrothrix* forms). On the other hand, von Freudenreich has ascribed these changes to the lactic-acid type of bacteria, which develop so luxuriantly in hard cheese.

Within the limits of this article it will be impossible to give a critical review of these theories that would do justice to the question at issue. But in view of important practical results recently obtained by Babcock and Russell, of the Wisconsin Experiment Station, it is

deemed advisable to review the theory promulgated by them and show its relation to their later work.

In 1897 they announced the discovery of an inherent enzym in milk which they termed *galactase*, and which has the power of digesting casein of milk and producing chemical decomposition products similar to those that normally occur in ripened cheese. The theory has been advanced by them that this enzym is an important factor in the ripening changes, and, as in their experiments bacterial action was excluded by the use of anæsthetic agents, they conclude that so far as the breaking down of the casein is concerned bacteria are not essential to this process.

In formulating a theory of cheese ripening, they have further pointed out the necessity of considering the action of rennet extract as a factor that is concerned in the curing changes. They have shown that the addition of increased quantities of rennet extract materially hastens the rate of ripening, and that this is due to the pepsin which is present in all commercial rennet extracts. They find it easily possible to differentiate between the proteolytic action of pepsin and galactase, in that the first-mentioned enzym is incapable of producing decomposition products lower than the peptones precipitated by tannin. They have shown that the increased solubility (ripening changes) of the casein in cheese made with rennet is attributable solely to the products peculiar to peptic digestion. The addition of rennet extract or pepsin to fresh milk does not produce this change unless the acidity of the milk is allowed to develop to a point which experience has shown to be the best adapted for the making of Cheddar cheese. The rationale of the empirical process of ripening the milk before the addition of the rennet extract is for the first time thus explained.

In studying the properties of galactase these investigators further found that this enzym, as well as those present in rennet extract, is operative at very low temperatures, even below the freezing point. These results have not yet been published, but were presented at a recent convention of the Wisconsin Cheese Makers' Association. When cheese made in the normal manner was kept at temperatures ranging from 25 to 45° F. for periods averaging from 8 to 18 months, it was found that the texture of the product simulated that of a perfectly ripened cheese, but that such cheese developed a very mild flavor in comparison with the normally cured product. Subsequent storage at somewhat higher temperatures gives to such cheese a flavor the intensity of which is determined by the period of storage. This indicates that the breaking down of the casein and the production of the flavor peculiar to cheese are in a way independent of each other and may be independently controlled, a point which is of great economic value in commercial practice.

Although it is generally believed that cheese ripened at low temperatures is apt to develop a more or less bitter flavor, the flavors in these

cases were found to be practically perfect. Under these conditions of curing bacterial activity is practically inoperative, and these experiments furnish an independent proof of the enzym theory.

Not only are these experiments of interest from the scientific point of view, as throwing light on the obscure processes of cheese curing, but from a purely practical standpoint they open up a new field for commercial exploitation.

The inability to control the temperature in the ordinary factory curing room results in serious losses on account of the poor and uneven quality of the product, and the consumption of this dairy product has been greatly lessened thereby. All of these conditions may be avoided by this low-temperature curing process, and it seems quite probable that the cheese industry is on the eve of important changes in methods of treatment.

With the introduction of cold-storage curing, and the necessity of constructing centralized plants for this purpose, the cheese industry will be differentiated into the manufacture of the product in factories of relatively cheap construction, and the curing or ripening of the cheese in central curing stations. In this way not only are the losses which occur in present practice obviated, but the improvement in quality of the cured product will be more than sufficient to cover the cost of cold-storage curing. It is important to note that this latest advance in methods as applied to commercial practice is the outgrowth of scientific studies on the theoretical side of the subject of cheese ripening, and well illustrates how dependent practice is on the pursuit of pure science.

The passage of the agricultural appropriation act for the year 1901-1902 marks an epoch in the history of the development of the national Department of Agriculture. Not only does it carry the largest appropriation ever made for the Department and provide for further extension of its work in various lines, but it inaugurates a scheme for the partial reorganization of the scientific branches of its work. Three of the present divisions are raised to the grade of bureaus, and a number of other divisions are associated into one large Bureau of Plant Industry, corresponding in a general way to the present Bureau of Animal Industry.

Starting first as an appendix to the Patent Office for the distribution of seeds, the Department of Agriculture was formally organized in 1862 as an independent department in charge of a commissioner, and in 1889 was raised to the dignity of an Executive Department. The passage of the Hatch Act providing for agricultural experiment stations about that time increased its responsibilities and extended its field of usefulness.

The growth of the Department has been steady and uninterrupted. The importance of its work has been recognized by steadily increasing

appropriations, and the relations maintained with the experiment stations furnish a means of carrying its investigations into every section of the country, in cooperation with these institutions, and serve to broaden its influence. As an institution for agricultural investigation it is now without a counterpart in any country, and there are few, if any, scientific institutions which include so large an aggregation of scientists and experts devoting their attention to investigation and research. The Department is coming to be generally recognized as one of the great scientific institutions, not alone in this country, but of the whole world. The formation of bureaus is a fitting step at this juncture, for it is a recognition of the growth which has been made and the need for a more compact form of organization. The creation of these four new bureaus, in addition to the Weather Bureau and the Bureau of Animal Industry, is a following out of the general divisions into which the subject of agriculture seems logically to fall, associating such lines of work as relate closely to each other and providing for the closest cooperation practicable among them.

The new Bureau of Plant Industry embraces the divisions of Botany, Vegetable Physiology and Pathology, Agrostology, Pomology, and Gardens and Grounds, and is under the directorship of B. T. Galloway. To this bureau has also been assigned the Section of Seed and Plant Introduction, together with the general supervision of the experiments in tea culture. A horticulturist will be added to the list of specialists, with the intention of developing the work of investigation along that line. From the standpoint of administration the arrangement will be an economy of time and will give greater opportunities for investigation to the chiefs of the divisions.

In recognition of the plan for a systematic survey of agricultural soils and for extension of the work in forestry, the divisions of Soils and Forestry are given bureau organizations and are raised to that designation. The fourth bureau provided for is the Bureau of Chemistry, to which additional scope will be given.

The appropriation act makes frequent mention of cooperation between the different divisions of the Department and also with the agricultural experiment stations. The establishment of the Bureau of Plant Industry will favor the extension of this cooperation and will assist in adjusting the lines of work and preventing any tendency to duplication.

Of the new bureaus the Bureau of Plant Industry receives the largest appropriation, namely, \$231,680. The amounts appropriated for the different lines of investigation in charge of this bureau, aside from certain salaries, are \$60,000 for investigations in vegetable pathology and physiology, \$20,000 for pomological investigations, \$45,000 for botanical investigations and experiments, \$20,000 for grass and forage plant investigations, \$20,000 for seed and plant introduction, \$7,000 for tea-culture experiments (an increase of \$2,000), and \$20,000 for

gardens and grounds. The total appropriation for the Bureau of Plant Industry represents an increase of \$61,900 over the combined appropriations for the previous year of the divisions associated in it. A new feature of the botanical investigations is the study of useful plants of the tropical territory of the United States, together with plants likely to be of value for introduction into those sections. Furthermore, investigations are to be made on "the varieties of wheat and other cereals grown in the United States and suitable for introduction, in order to standardize the naming of varieties as a basis for experimental work of the State experiment stations and as an assistance in commercial grading;" and in cooperation with the Bureau of Chemistry the cause of deterioration of export grain, particularly in oceanic transit, is to be investigated, together with means of preventing such loss. Special mention is made in the appropriations for this bureau of the employment of scientific aids, a class of employees drawn from the Agricultural Colleges, which has previously been arranged for in the Department.

The Bureau of Forestry receives \$185,440, an increase of \$105,440 over the previous year. The appropriation for the Bureau of Soils is \$109,140, which is an increase of \$77,840. This is to enable an extension of the tobacco investigations, which remain in charge of this bureau, and the investigation and mapping of soils in the United States. The Bureau of Chemistry receives \$35,800, and in addition to its other duties is charged with the investigation of food preservatives and coloring matters "to determine their relation to digestion and to health and to establish the principles which should guide their use."

The Weather Bureau receives increased appropriation for general maintenance, and \$46,000 for the erection and equipment of buildings in six different places, and for laying a cable between the mainland and Tatoosh Island, Washington, making the total appropriation \$1,148,320. The maintenance fund of the Bureau of Animal Industry is increased \$50,000, and the inspection work is extended to include dairy products intended for exportation to foreign countries. Such products, the same as meats, may be marked, stamped, or labeled, so as to secure their identity and indicate their purity, quality, and grade. This is an entirely new provision, which it is hoped will tend to place American dairy products on a better footing in foreign markets. An appropriation of \$25,000 is made, in addition to one of \$50,000 last year, for animal quarantine stations, giving a total for the bureau of \$1,154,030.

The appropriations for agricultural experiment stations has reached the sum of \$789,000, including \$33,000 for the Office of Experiment Stations, as heretofore, and \$12,000 each for stations in Alaska, Hawaii, and Porto Rico. The Hawaii station will be located near Honolulu on a Government reservation originally set apart by the provisional government for the use of an experiment station. It is intended to make the work there supplementary to that of the experi-

ment station which has been maintained by the Hawaiian sugar planters, and attention will be given to other field crops and the development of animal industry and horticulture. Jared G. Smith, recently in charge of the Section of Seed and Plant Introduction of this Department, has been placed in charge of the Hawaii station, and will take up the work there about the middle of April. Fifty thousand dollars was appropriated to continue the irrigation investigations, and \$20,000 for nutrition investigations, the latter being an increase of \$2,500.

The Division of Statistics receives \$156,160, the same as last year, the Division of Entomology \$36,200, and the Division of Biological Survey \$32,800. The fund for publications is increased by \$50,000 for farmers' bulletins and a small amount for distribution, making the total for the Division of Publications \$198,020 aside from the general printing fund, \$110,000. Other appropriations are as follows: Seeds \$250,000, exclusive of the \$20,000 mentioned for seed and plant introduction, an increase of \$100,000; library, \$16,000; public-road inquiries, \$20,000, an increase of \$6,000; investigating the production of domestic sugar, \$5,000; Arlington farm, \$10,000; office of the Secretary, \$71,670; Division of Accounts, \$18,900; Museum, \$2,260, and contingent expenses, \$37,000. The grand total, including the regular appropriations for the experiment stations, is \$4,582,420, an increase of \$558,920 over last year.

An important item of the appropriation act is the authorization of the Secretary of Agriculture to submit plans and recommendations for a fireproof agricultural building, to be erected on the grounds of the Department, and appropriating \$5,000 for the preparation of such plans. The Department long since outgrew its original accommodations, and for years has been badly cramped for room. The present main building has been condemned as unsafe, and from the nature of its construction the risk of fire has always to be met. Besides erecting a number of small buildings, which are mere temporary makeshifts, it has been necessary to rent several residences in the neighborhood and adapt them to laboratory and office purposes. Laboratory buildings for the Division of Chemistry and the Bureau of Animal Industry have been specially erected by private parties and rented to the Department. The amount now paid for rental for these buildings, together with the additional expense required for watchmen, aggregates about \$10,000 annually. The position to which the Department has now attained, the demands of its work, and the safety of its library, records, and collections, make a modern agricultural building a practical necessity if not an imperative need.

RUSSIAN SOIL INVESTIGATIONS.¹

In the previous article the system of soil classification adopted by Dokouchayev and his collaborators was explained. This classification was in brief as follows: (1) Zonal soils, including lateritic soils, eolian or loess soils, soils of the dry steppes, chernozem, gray forest soils, sod and podzol soils, and tundra soils; (2) intrazonal soils, including alkali, humus-calcareous and marsh or swamp soils; (3) incomplete or azonal soils, including crude and skeleton soils, and alluvial soils. The following article discusses the characteristics of these various types of soils as they occur in Russia.

BRIEF SURVEY OF THE CHIEF SOIL TYPES OF RUSSIA.

ZONAL SOILS.

Russia, being a country of temperate and cold climates, has no lateritic soils.

Loess soils.—Loess or eolian soils occur in the hot, windy, dry climates of Turkestan and the trans-Caspian region, alternating with sandy and alkali soils. The loess soils are yellowish, bright orange, or straw colored. The percentage of humus does not exceed 2.5, and is usually less than 1. About one-half of the soil particles are less than 0.01 mm. in diameter. The other half is usually a mixture in which particles ranging in diameter from 0.01 to 0.05 mm. predominate. In a grayish loess soil from the vicinity of Tashkend there was found fine sand 65 per cent, ferric oxid 3.6, alumina 10, calcium carbonate 7 to 15, potash 2.8, and phosphoric acid 0.28 per cent. The amount of zeolites present ranged from 15 to 20 per cent and more. Loess or eolian dust soils are widely distributed, *e. g.*, not only in the Aral-Caspian basin, but in China, northwestern India, Arabia, Africa, and the drier portions of North America.

Soils of the dry steppes.—In European and Asiatic Russia, between the loess and chernozem, are found the brown and chestnut soils of the dry steppes. The area occupied by these soils in European Russia includes the vast regions between the Ural River and the lower Volga (with the exception of the sandy soils) and between the lower Volga and the district of Manitch, extending also into the steppes of Crimea

¹ Concluded from p. 712.

and over the coast of the Black Sea. In Asiatic Russia these soils cover parts of Uralsk, Turgai, Akmoïinsk, and Semipalatinsk. The annual rainfall of this soil zone varies from 30 to 40 cm., one-third of which occurs during the three summer months. The natural vegetation consists mainly of drought-resisting grasses and other plants which dry up early in the season and are driven about over the steppes by the winds. The predominating parent rocks of these soils are brownish, greenish gray, and reddish Post-Tertiary clays, compact, frequently marly, and containing gypsum and soluble salts in some instances. In other cases they are loess-like or sandy. Rock fragments, pebbles, etc., are also found in the soils. The conditions in this soil zone are not favorable to rapid weathering. Light brown or brown-gray soils, poorer in humus, occupy the southern or more strictly desert portion of the belt. The chestnut soils, richer in humus, and merging into the chernozem, are found in the northern portion. The upper horizon of the first class of steppe soils is not more than 1 ft. in depth and gradually merges into the subsoil. The humus content is variable, but averages about 2 per cent. The humus is very slightly soluble in water except when alkaline salts are present. The richness of the humus in nitrogen is a characteristic feature of these soils. In a sample of steppe soil which contained only 1 per cent of humus there was found 0.12 per cent of nitrogen, equivalent to 12 per cent of nitrogen in humus. A similar observation has been made by Hilgard regarding the nitrogen content of the humus in soils of the arid region of America (E. S. R., 6, p. 197). The amount of zeolites found varied from 8 to 12 per cent. The amount of matter soluble in cold 1 per cent hydrochloric acid, excluding the carbonates, was $1\frac{1}{2}$ to 2 per cent. The upper horizon of the chestnut soils is from 1 to $1\frac{1}{2}$ ft. deep. These soils contain on the average from 3 to 4 per cent of humus, the amount sometimes being as high as 5 per cent. From 2 to 3 per cent of the soil is soluble in cold 1 per cent hydrochloric acid. A bulk analysis of subsoil from this zone showed silica 68.2 per cent, alumina 11.56 per cent, iron oxid 3.56 per cent, lime 4.63 per cent, magnesia 1.92 per cent, potash 1.98 per cent, soda 1.36 per cent, carbon dioxid 3.74 per cent, and phosphoric acid 0.15 per cent. Similar soils are found in California, Colorado, New Mexico, and other parts of the arid region of the United States.

Chernozem.—The southern third of European Russia is preeminently a region of chernozem. The area occupied by it reaches approximately 216,000,000 to 270,000,000 acres. The chernozem zone extends from the southwestern boundaries of Russia, over the basins of the Dnieper, Don, and part of the Volga, to the southern half of the Ural Mountains. It also extends beyond the Ural River and into Asiatic Russia, although it does not form a continuous belt over the mountainous region of eastern Siberia. All of the chernozem soils of Russia are found between 44 and 57° north latitude.

The chernozem territory is an undulating plain with occasionally extensive elevations and furrowed by ravines and river valleys. There is no doubt that in prehistoric times it was flatter and more uniform than at present. The climate is preeminently continental, but with less pronounced characteristics than in the zone of the dry steppes. The annual rainfall fluctuates between 40 and 50 cm., 30 cm. occurring during the period of plant growth. Agriculture suffers occasionally from droughts and from high winds which are sometimes intensely cold and at other seasons hot and dry. It is believed that at an early period of the history of the steppes, when their surface was more uniform and retained the cover of dead vegetation, the moisture conditions of the soil during winter were better than they are at present, although it is not likely that there was ever an excess of water. The chernozem zone of southern Russia has never been an uninterrupted swamp, as has been maintained by some scientists who believe the chernozem to be derived from the decomposition of peat. It was a prairie with a luxuriant growth of grass. Its natural plant cover consisted mainly of thick tall grasses interspersed here and there with bushes and shrubs. There were originally no forests except on the sandy strips and in the river valleys. The investigations of Ruprecht, Middendorf, Krasnov, Tanfilyev, Korzhinski, and other geobotanists have explained the complex character of the vegetation of these steppes meadows.¹

Chernozem is as a rule formed by the admixture of humus with loess, but it is also sometimes derived from other parent rocks. In general, it may be stated that calcareous formations which yield fine particles on weathering are more favorable than other rocks to the formation of chernozem. In addition to this, there must be a particular combination of topography, vegetation, climatic conditions, etc., favorable to the accumulation of humus in the soil. Chernozem is usually black, the shade varying in intensity and passing sometimes into chocolate and cinnamon. Its average depth is about a meter, but this varies, the sandy chernozems being generally deeper than the clayey. The structure of the uncultivated soil is granular, the aggregates being from 2 to 4 mm. in diameter. As the soil merges into the subsoil this structure disappears and the soil becomes more compact and irregular in color, gradually assuming a brown color as it merges into the parent

¹ The list of plants growing on these steppes includes *Adonis vernalis*, *A. wolgensis*, *Paeonia tenuifolia*, *Lavatera thuringiaca*, *Linum perenne*, *L. flavum*, *Medicago falcata*, *Aster amellus*, *Trifolium* spp., *Oxytropis pilosa*, *Onobrychis sativa*, *Vicia tenuifolia* (and others), *Centaurea marschalliana*, *C. rathenica*, *Scorzonera purpurea*, *Hieracium virosum*, *Campanula sibirica*, *Echium rubrum*, *Lychnis chalcedonica*, *Thymus marschallianus*, *Salvia pratensis*, *S. nutans* (and others), *Nepeta nuda*, *Phlomis tuberosa*, *Ajuga genevensis*, *Euphorbia procera*, *Asparagus officinalis*, *Poa pratensis*, *Festuca ovina*, *Stipa pennata*, *S. capillata*, and others.

rock. The percentage of humus is quite variable, but in general declines quite uniformly from the center toward each edge of the chernozem zone. This variation is so uniform that it has been utilized by Dokouchayev in the establishment of so-called isohumic bands.

On the basis of humus content the chernozem may be divided into four genetic subtypes: (1) The humus or rich chernozem of the eastern central belt, which contains more than 10 per cent of humus; (2) the medium or ordinary chernozem, which occupies the larger part of this soil zone and contains 6 to 10 per cent of humus; (3) the southern chocolate-colored chernozem, which merges into the chestnut soils of the dry steppes, containing 4 to 6 per cent of humus; and (4) the northern cinnamon-colored chernozem of central Russia, which occurs in strips and spots, alternating with forest and light loess soils, and which contains 3 to 6 per cent of humus.

The chernozems also show wide variations in the composition of their mineral constituents, being clayey, sandy, calcareous, peaty, alkaline, etc., according to the sources from which they are derived or the conditions of their formation. The humus is but slightly soluble in water. The total nitrogen content varies from 0.2 to 0.7 per cent in the soil or from 5 to 8 per cent in humus. The clay content varies from 20 to 40 per cent, zeolites from 15 to 35 per cent. Cold 1 per cent hydrochloric acid dissolves from 3 to 5 per cent of matter from the soil, excluding carbonates. The absorptive power varies from 20 to 43 per cent. The silicates of chernozem have undergone a high degree of weathering and decomposition. Thus, of the 2 to 2.4 per cent of potash, from one-fifth to one-half dissolves in 10 per cent hydrochloric acid. Of the 8 to 10 per cent of alumina from one-half to four-fifths dissolves in the same reagent. The phosphoric acid varies from 0.12 to 0.3 per cent. In the upper horizon of the soil the carbonates, mainly calcium carbonate, do not usually exceed 1 to 3 per cent, but in chernozems derived from limestones the carbonates sometimes reach 10 to 15 per cent. The sandy portion of the chernozem is very fine, consisting of quartz, with an admixture of mica, feldspar, and other silicates. According to Kostichev, the mineral portion of chernozem, excluding the carbonates, is very similar in composition to the loess from which it is derived, there being a slight increase of phosphoric acid, due to the accumulation of humus. In the foothills of the southern Ural Mountains there occurs a variety of chernozem which contains as much as 2 per cent of phosphoric acid.

It may be said in general that the chemical properties of chernozem are more favorable than the physical. The particles are as a rule too fine, from 60 to 80 per cent of the particles being ordinarily less than 0.05 mm. in diameter, and the proportion of silt (particles less than 0.01 mm. in diameter) sometimes reaches 58 per cent. Particles larger than 0.5 mm. in diameter are either entirely absent or present in very

small quantities. As long as the chernozem preserves its natural granular structure the high percentage of fine particles has comparatively little influence upon its relation to water, but in cultivation under the climatic conditions prevailing in the steppes of southern Russia these soils to a large extent lose this structure and consequently present the properties of fine porosity, high capacity for absorbing and retaining water, and low permeability. With irregular rainfall followed by droughts the moisture of the surface soil has been observed to decrease to 6 per cent (one-seventh of its water capacity), and the soil dries and hardens, resulting occasionally in serious failures of crops.

The chernozem of Siberia has not been very fully studied. Analysis shows that it contains from 5 to 11 per cent of humus and from 0.28 to 0.6 per cent of nitrogen. In the clayey types there is from 15 to 25 per cent of zeolites, 7 to 10.5 per cent of alumina soluble in sulphuric acid, and 0.16 to 0.28 per cent of phosphoric acid. The soils of the Amur prairies are generally richer in humus than the ordinary chernozems of Russia. Soils of the chernozem type are found alternating with alkali lands and sandy soils in Banat and in the plains of eastern Hungary, which are separated by the Carpathian Mountains from the steppes of southern Russia.

The chernozem zone also embraces a considerable part of the United States. The soils of the humid prairies in Wisconsin, Minnesota, Iowa, Missouri, and other States are quite similar in character to the chernozems of the Amur region. In States such as the Dakotas, Montana, Nebraska, Kansas, and Arkansas, where the rainfall is deficient, the soils are similar to the ordinary and the chocolate colored chernozems of the steppes of southern Russia. In the more strictly arid States, such as Arizona, southern California, etc., are found analogues of the chestnut and light brown soils of Russia.

It is of interest to note that there is a southern chernozem zone represented by the soils of the pampas of Argentina. Especially fine examples of this type of soil are found in the Province of Entrerios.

Gray forest soils.—Under this name are included the soils of the wooded steppes, adjoining the chernozem or even penetrating far into the region of chernozem, but which have been modified by forest vegetation. They merge by a gradual transition into chernozem on the one hand and peaty soils or podzols on the other. They extend in a narrow, rather regular, not always continuous belt across central Russia from the governments of Lublin and Volinsk on the west to the basin of Kama and Viatka on the east. In the chernozem zone they are found usually along the rivers and valleys, where the soils are well drained and free from alkali. The observations of soil experts and geobotanists show concordantly that fine grained soils, which possess a great capacity for humidity and a low degree of permeability, and those

which contain a large amount of soluble salts are unfavorable to forest growth, particularly if the soils receive a limited supply of moisture; but that as soon as these conditions are corrected and the forest vegetation has gained a foothold in the steppe on the slope of some ravine, it is at once in condition to protect itself against the unfavorable climatic and soil influences. It gathers the snow, moderates the winds, lowers the range of the temperature, prepares for itself the soil necessary for its growth, and advances little by little into the neighboring steppe. The different stages in this process of transformation of chernozem may be observed in progress under natural conditions and may be duplicated under artificial conditions. Prof. Kostichev filled a cylindrical vessel with chernozem, covered it with a layer of leaves, and maintained it in a moist condition. In three years the chernozem was transformed into a gray soil with $2\frac{1}{2}$ per cent of humus.

The upper horizon of these soils in virgin condition is $1\frac{1}{2}$ to 3 dm. in depth, gray, gray-cinnamon, or dark gray in color and almost structureless. The lower horizon, 3 to 4 dm. and more in depth, is ash-gray, sometimes friable, but more frequently of a crumby structure. It consists of brown-gray rounded or polyhedral aggregates mixed with fine quartz and siliceous flour. An admixture of humus gives to this powder an ash-gray color. Lower down the aggregates become larger, the amount of the ash-gray powder decreases, and the horizon, gradually assuming a brown color, merges into the subsoil.

The parent rocks (subsoils) of the forest lands are usually weathered morainic clays, diluvial clays (sometimes loess-like), leached loess, and ancient sedimentary rocks—clays, marls, etc.—also weathered and leached.

The content of humus fluctuates in the upper horizon between 3 and 6 per cent; in the lower horizon it rapidly falls to 2 and even 1 per cent. The solubility of the humus in water is greater than in the case of the chernozem. The total amount of nitrogen varies from 0.01 to 0.16 per cent (4 to 5 per cent of the humus). The amount of zeolites does not exceed 20 per cent, frequently falling as low as 16 or 12 per cent. The total amount of mineral substances decomposed by 1 per cent cold hydrochloric acid is ordinarily about one-half that found in chernozem. The potash varies from 1 to 2.4 per cent, lime from 0.4 to 1 per cent, and phosphoric acid from 0.1 to 0.14 per cent. As high as 0.28 per cent of calcium carbonate has been observed. The soils are much less soluble in 10 per cent hydrochloric acid than chernozem.

The ash-colored powder of the lower horizon is considered to be a product of the action of humus acids upon the silicates, causing the separation of a part of the silica in pulverulent form.

The mechanical composition of these soils is variable. In the forest subclays of the Nijni Novgorod, Orlov, or Poltava governments the amount of particles less than 0.01 mm. (20 to 25–32 per cent) was to that of the larger ones (80 to 75–68 per cent) as 1:4, 1:3, 1:2. The

general absence of structure of the upper horizon contributes to its pulverization in plowing, resulting in an increased capacity for humidity and decreased permeability.

The subclays of the wooded steppes occupy in all respects an intermediate position between the chernozem and the "forests" subclays proper, approaching first one then the other in character. By a study of the distribution of the forest subclays and the subclays of the wooded steppes in the territory of the chernozems Dokouchayev was able to determine the areas which have been in the past occupied by forests, but which are now under cultivation. Tanfilyev has lately prepared a map of the prehistoric steppes of European Russia. Wooded steppes and true forest soils extend into Siberia. Soils identical with or very closely resembling them are also found on the plains of western Europe, namely, in Galicia, Hungary, and in central Germany. There is little doubt that this type of soils occurs on the American continent where the prairies begin to be replaced by forests.

Sod and podzol soils.—The Russian term "podzol" very nearly corresponds with the German "Bleisand" (lead sand), with this difference, however, that the term is applied not only to sandy but also to more sticky, clayey soils if they have been affected to a marked degree by chemical leaching processes under the influence of the solvent action of humus acids. In the regions where podzol soils occur the climatic and other conditions are especially favorable to the decomposition and leaching of the soil constituents by the solvent and reducing action of the humus.

The upper horizon of the podzol is light gray or gray, frequently with a light cinnamon tint, and 1 to $1\frac{1}{2}$ decm. in depth. It has no marked structure, and its coherence varies with the content of clay, sand, and humus.

The underlying horizon is much lighter, sometimes almost white, sometimes with a yellowish or pale-blue tint. This is the podzol proper. It presents a mass of fine particles, flour-like in a dry state, sticky in a wet state, very rich in silica. The thickness (depth) of the podzol layer varies from a few centimeters to over 4 decimeters. The subsoil or the parent rock is most frequently red-brown sandy morainic clay with pockets of podzol, or argillaceous sand, but the subsoils may also be pebbly clays, feebly coherent and friable sands, clay or loamy yielding rocks, or even loess-like deposits.

When the second horizon is near the surface the whole soil is called podzol; when it is not individualized, indistinct, or entirely absent, a sod or peat soil results. Between the first and the second there exist in nature gradual transitions, as can be seen in northern Russia on every cultivated field and under every forest.

Concretions are ordinarily found in podzol soils in the form of bullet-like grains, small veins, or continuous layers in the lower part of the

second horizon or at the border between the latter and the parent rock.

The soils of this group occupy not less than two-fifths of the area of European Russia, the greater part of Poland being included. At the north they extend as far as Archangel and penetrate in strips and circumscribed areas into the borderland of the tundra soils. At the south they comprise parts of the governments of Perm, Kazan, Nijni Novgorod, Vladimir, Riazan, Kaluga, Oryol, Chernigov, Volyn, and Lublin, where they intermix with the forest subclays and the chernozem. Typical podzols are found especially in the governments of Mogilyov, Smolensk, Vitebsk, Tver, Novgorod, Pskov, and St. Petersburg.

In podzol soils which were once covered with woods and are now cultivated the content of humus is not large, varying from a few tenths of 1 per cent to 2 or 3 per cent, rarely more.¹ In the lower horizon the amount of humus rapidly falls to 0.1 to 0.3 per cent. The nitrogen fluctuates between 0.1 and 0.15 per cent in the upper horizon. The solubility of the humus is remarkably high. From soil of the upper horizon water extracts from one forty-eighth to one-twentieth of the total humus and of the lower horizon from one twenty-seventh to one-tenth. Nitric acid is often found in these extracts.

The soils contain on an average 95 to 97 per cent of mineral matter, of which 80 per cent and more is silica. The amount of zeolites usually does not exceed 10 to 12 per cent, frequently falling much lower (7 to 5 per cent); the amount of substances soluble in 1 per cent cold hydrochloric acid is rarely more than 2 per cent. The total quantity of phosphoric acid varies from 0.05 to 0.08 per cent, but is larger in soils containing a large amount of organic matter. The investigations of Kostichev have proved that in this case it is present mainly in combination with the humus. The absorptive capacity does not in general exceed 12 to 13 per cent.

The podzol soils vary widely, according to the nature of the parent rock. The composition of samples of three different horizons of a podzol soil from the Novgorod Government is given in the following table:

Composition of a podzol from the Novgorod Government.

	Humus.	Lime.	Mag- nesia.	Alumina.	Iron oxid.	Phosphor- ic acid.	Silica.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Upper horizon.....	2.8	1.172	0.378	7.032	1.84	0.085	81.02
Lower horizon (podzol proper).....	.3	.790	.240	4.790	.67	.050	90.70
Subsoil.....		1.030	.340	7.210	1.62	Undeter- mined.	84.50

¹ If the upper horizon is turf-like it contains sometimes up to 15 per cent and more of partly decayed organic matter.

If the second horizon is near to the surface or the whole soil is transformed into podzol the land is, of course, very poor. In sandy soils the second horizon contains much less of the alkalis, lime, magnesia, iron oxid, alumina, and phosphoric acid than is found in clayey soils of this class.

The relation of sand to fine earth in podzol soils varies from 5:1 to 7:1. The capacity for water is only from one-half to two-thirds that of chernozem, while its permeability is 2 to 6 times as great. On the better class of podzol soils, when well provided with moisture, the crops, although not large, are more uniform and constant than on the chernozem, especially if well fertilized. In the true silty podzol, however, there is frequently more than 70 per cent of fine earth in the form of quartz dust. It absorbs moisture with avidity and retains it for a long time, turning into a sticky dough-like mass. On drying it breaks up into dust or hardens and forms crusts. This is one of the worst and most unproductive soils, both on account of its poverty in fertilizing constituents and of its unfavorable physical properties.

Soils of the podzol type are found in Siberia, northern Germany, France (the landes), Holland, Denmark, and Scandinavia, and North America (mainly in the British possessions).

Tundra soils.—The soils of the arctic tundra of European Russia and Siberia may be classified as rocky, turfy, clayey, and sandy. The level surface and the treeless condition of the tundra of the basins of the Petchora, Obi, and Yenisei Rivers impart to it a steppe-like appearance. The vegetation consists of lichens, mosses, *Arctostaphylos*, *Andromeda*, *Empetrum*, *Rubus chamaemorus*, *Vaccinium*, *Carex*, etc. *Betula nana* and the polar dwarf willows appear as almost the only representatives of bushes. The humus is crude and accumulates only in the surface horizon of the clayey or sandy soil, to a depth of 3 to 5 cm.; everywhere can be seen denuded places, surrounded by mosses or lichens. The temperature fluctuations are striking. The summer is very short; even in July the temperature falls at night to $+3^{\circ}$ C., and at the end of the month even to -2° ; in August it snows, and soon the long winter, with its icy winds, begins. The perpetually frozen layer begins in the clayey tundra at a depth of 0.7 to 1 meter and in the sandy at a depth of about $1\frac{1}{2}$ meters. The turfy tundras are characteristic mounds of turf, frozen inside, which are 15 to 20 meters in length and 4 meters in height. The forest penetrates into the tundra from the south, along the river banks, where the perpetually frozen horizon is deeper than in other places.

INTRAZONAL SOILS.

Alkali soils.—Alkali lands are found in the southern part of European Russia, in southwestern Siberia, in the Transcaspiian region, and in Turkestan. In the territory of the chernozem they occur in spots,

usually on the gently sloping southern declivities or on the slight depressions of the steppes. Sometimes these areas occupy dozens of square kilometers and contain saline lakes, but more frequently they are scattered over the steppes in small spots. In a vertical section of a chernozem alkali soil there are seen: (a) The upper horizon, black, dark gray, dark brown, or gray, sometimes homogeneous, sometimes pervaded by a whitish dust; from 1 to 3 dm. deep; (b) a light gray or whitish horizon, 1 to 3 dm. deep (sometimes almost absent), merging into (c) a brownish or yellowish compact and sticky clay.

On the surface of the alkali soil, especially after a rain, appear efflorescences or crusts consisting of whitish siliceous powder and minute saline crystals. The content of humus in the upper horizon is in general much less than in the adjacent chernozem, but sometimes reaches 8 per cent and more. The water extracts are colored light cinnamon or light cherry from the alkaline humates in solution. The solubility of the humus reaches one-seventieth in the upper horizon and one twenty-fifth in the second horizon (b), *i. e.*, it is twice or three times as great as in the chernozems. This is due to the greater humidity of the alkali soils and brings them into close relation with the soils of the podzol type. The whitish color of the lower horizon and the siliceous dust of the efflorescences and crusts is due to the same cause. Of the mineral salts soluble in water in the alkali soils of the chernozem zone there occur sodium carbonate, sodium sulphate, sodium chlorid, calcium sulphate, magnesium sulphate, and calcium bicarbonate. Many alkali soils are marly. The total amount of salts extracted by water varies according to Kostichev and others from 0.5 per cent to 5 per cent and more. With regard to physical characteristics, the alkali soils of the chernozem territory are distinguished by becoming very compact and hard upon drying.

The alkali soils of the dry steppes and of Turkestan are mostly yellowish and brownish in color, like the zonal soils which surround them, but dark colored alkali soils are also met with. The white incrustations consist of sodium sulphate, sodium chlorid, magnesium sulphate, calcium sulphate, and carbonates. Extensive alkali deserts without any cultivation whatever occur, as well as saline mud flats.

In general the alkali lands of European and Asiatic Russia bear a close resemblance to those of Hungary, India, Arabia, the western States of North America, Argentina, Australia, and other level and dry regions.

Humus-calcareous soils.—The soils which are formed from limestones and marls are frequently skeleton soils and contain little humus, especially if distributed over steep river banks and along ravines, but from the same parent rocks—soft limestones, chalk, and chalky marl—originate gray and dark gray soils, sometimes very rich in humus. In the southern part of Poland they attract especial attention, being in

marked contrast with the surrounding light gray podzol soils. They are known under the local terms of "rendzina" or "borowina." The upper horizon of the rendzina is most frequently gray, without a cinnamon tint, not rarely spotted with white undecomposed chalk; lower down the color becomes lighter and the soil gradually merges into the marly, sticky clay which is mixed with chalky gravel. Still lower lies the white parent rock—chalk or limestone. The content of humus varies from 3 to 5 per cent and more; its solubility from one one-hundredth to one one-hundred-and-thirtieth. The amount of calcium carbonate varies from 3 to 17 per cent and more. The clayey character of the mineral matter renders the soil sticky in wet weather and hard in a drought. However, lighter sandy rendzinas also occur.

Marsh or swamp soils.—Soils of this type extend largely throughout the whole northern half of Russia, but are of little economic importance. In the basin of the Pripet River they occupy more than 2,000 square kilometers. Throughout the podzol soil areas spots and strips of grassy marsh soils are formed under the influence of excessive stagnating water. The vegetation consists of species of *Carex*, *Scirpus*, *Phragmites*, *Acorus*, *Menyanthes*, *Parnassia*, *Nasturtium*, *Ranunculus*, *Butomus*, *Sagittaria*, etc. The roots of these plants penetrating into the slimy mineral rock oversaturated with water, give humus which slowly oxidizes and which accumulates in large amounts (4 to 20 per cent). The borders of the marshes are frequently cultivated and are known as "black earth" in contrast to the adjacent light sod and podzol soils.

The thickness of the dark-colored horizon varies from 2 to 8 and more decimeters. The solubility of the humus of the soil as a whole is not great ($\frac{1}{210}$ to $\frac{1}{270}$), but rapidly increases with the depth in the soil, being one-tenth at a depth of 1 meter. The abundance of moisture which dissolves humus acids favors the decoloration and leaching of the lower horizons of the soil, making them very similar to the podzols. Under the marshes are frequently found white, light gray, or bluish, and grayish-white slime, either clayey or sandy. The total quantity of nitrogen in the upper horizon varies from 0.3 to 4 per cent.

In the mineral part of the soil the proportion of the clay and sand is variable. Brown veins and concretions of limonite, vivianite, iron sulphid, etc., are usually present. A considerable amount of carbonate and sulphate of calcium are also characteristic of many marshy soils which contain animal remains (shells of mollusks, etc.).

INCOMPLETE OR AZONAL SOILS.

To this class belong the crude and skeleton soils originating from compact, pebbly, conglomerate, and sandy rocks, and morainic and alluvial soils, which are more or less widely distributed throughout

Russia. The Russian rivers, with the exception of some which flow through mountainous regions, overflow regularly in the spring. The alluviums which they deposit consist of sands, clays, and sandy or marly clays, containing some limonite, peat, vivianite, etc.

The prairie vegetation which springs up after the water has receded results in an accumulation in the upper horizon (soil proper) of varying quantities of humus.

The petrographic character of these soils approaches that of the soils from which the alluvium is derived—in northern Russia the podzols, in southern the chernozems.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The qualitative detection of mineral phosphates in Thomas slag, N. VON LORENZ (*Ztschr. Landw. Versuchs. Oesterr.*, 3 (1900), p. 684; *abs. in Chem. Ztg.*, 24 (1900), No. 96, *Repert.*, p. 355).—A filter paper about 5 cm. in diameter is moistened with about 1 cc. of 5 per cent soda solution and spread over the convex side of a large watch glass which is suspended for about 5 minutes over a beaker in which 10 gm. of the Thomas slag has been stirred up with 30 cc. of concentrated sulphuric acid. The filter paper is then washed off into a beaker with 2 to 3 cc. of water and the solution tested for fluorin with calcium chlorid in presence of acetic acid. The presence of fluorin is taken to indicate the presence of mineral phosphates.

Estimation of alkali carbonates in the presence of bicarbonates, F. K. CAMERON (*Amer. Chem. Jour.*, 23 (1900), No. 6, pp. 471-486).—Titration in the cold with a solution of acid potassium sulphate, using phenolphthalein as an indicator, is claimed to give satisfactory results in the examination of alkali soils. The reaction which occurs is as follows: $\text{Na}_2\text{CO}_3 + \text{H}_2\text{SO}_4 = \text{HNaCO}_3 + \text{NaHSO}_4$. The reaction products are neutral to ordinary indicators. Chlorin may be determined in the solution after the determination of the carbonate by adding a slight excess of the sulphate and titrating with silver nitrate solution, using potassium chromate as indicator. The method also seems to be adapted to the determination of silicates, borates, phosphates, and the salts of weak acids in general.

Methods of determining proteid nitrogen in vegetable materials, G. S. FRAPS and J. A. BIZZELL (*North Carolina Sta. Bul.* 174, pp. 95-104).—The authors report a study of phospho-tungstic acid and bromin as precipitants for the proteids of vegetable materials. The phospho-tungstic acid method as proposed by Mallet and the bromin method as proposed by Wiley for animal materials (*E. S. R.*, 10, p. 819) were modified and compared in a series of determinations with the copper hydroxid method as proposed by Stutzer and adopted by the Association of Official Agricultural Chemists. A variety of vegetable and animal materials were used in the comparative determinations. Tests were made of the effect of temperature and of the quantity of

the reagent used in the phospho-tungstic acid method. Zinc sulphate as a precipitant of proteids was also compared with the reagents on several materials. The following conclusions are drawn:

"Phospho-tungstic acid does not precipitate proteids completely at 90 or 100° C.

"With phospho-tungstic acid as the precipitant, at 60°, very nearly the same results are obtained on vegetable materials as by the Stutzer method.

"Bromin is not a suitable precipitant for proteids in vegetable materials.

"The Stutzer method seems to be the method least open to objections."

A new method for the determination of nitric nitrogen, J. F. POOL (*Jour. Pharm. et Chim., 6. ser., 11 (1900), No. 6, p. 285; abs. in Ann. Agron., 26 (1900), No. 11, p. 585*).—The solution containing the nitrate is evaporated to dryness with sodium chlorid and decomposed with sulphuric acid in an atmosphere of carbon dioxid. The hydrochloric and nitric acids thus formed react upon each other, liberating chlorin according to the following formula:

The chlorin is driven off from the solution, after dilution, and conducted into a solution of potassium iodid, the iodine set free being determined by titration with sodium hyposulphite. From the data thus obtained the nitrogen present is calculated by means of the above equation.

Estimation of nicotin, amount of nicotin in New South Wales tobaccos, G. HARKER (*Chem. News, 81 (1900), p. 273; abs. in Jour. Chem. Soc. [London], 78 (1900), No. 477, II, p. 778*).—Comparative tests were made of the methods of Kissling and Biel. The original forms of these methods gave similar results, but the modification of Biel's method involving the weighing of the double sulphates of nicotin and ammonia did not give satisfactory results. The same was true of attempts to estimate nicotin volumetrically in the presence of ammonia. No loss of nicotin was observed during the evaporation of its solutions in ether. Four varieties of New South Wales tobacco examined gave the following percentages of nicotin: Manila, 1.95; Tamworth, 2.36; Tumut, 3.84; and Bathurst, 4.53.

The adulteration and analysis of the arsenical insecticides, J. K. HAYWOOD (*Jour. Amer. Chem. Soc., 22 (1900), No. 9, pp. 568-582*).—The author reviews the work reported by a number of the experiment stations on the composition and adulteration of insecticides and reports trials of a number of methods of analysis that have been suggested. His conclusions are as follows:

"(1) Water can be determined in Paris green and Scheele green by drying at the temperature of boiling water for 12 to 15 hours.

"(2) The best method for determining the total arsenious oxid in Paris and Scheele greens is the Thorn-Smith method [*E. S. R.*, 11, p. 614].

"(3) The best method for determining the soluble arsenious oxid in Paris and Scheele greens is by extracting with 500 cc. of water at room temperature.

"(4) Hot water extraction can not be used to extract soluble arsenious oxid.

"(5) A good method for determining copper in Paris and Scheele greens is the volumetric method based on the titration of the iodine set free from potassium iodide by a copper salt in acetic acid solution."

Composition and analysis of London purple, J. K. HAYWOOD (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 12, pp. 800-809).—The author finds London purple to consist of calcium arsenite, calcium arsenate, and an organic dye.

After a trial of several methods of analysis the following was found very satisfactory in determining the arsenic in London purple: Two grams of substance is dissolved in 80 cc. water, 20 cc. hydrochloric acid added at 60 or 70°, and the whole filtered and washed to a volume of 300 cc. An aliquot of 100 cc. is treated with sodium carbonate in excess and made up to 500 cc., using a few drops of ether to destroy bubbles; 250 cc. of this solution is filtered, starch solution added and a standard iodine solution until the blue color appears. The result represents the arsenious oxid as such in 50 cc. of the original solution or in $\frac{1}{3}$ gm. substance.

To determine the total amount of arsenic 50 cc. of the original solution, representing $\frac{1}{3}$ gm. of substance, is heated in a water bath to 80°, after which 50 cc. of hydrochloric acid and 3 gm. of potassium iodide are added. After standing 15 minutes the arsenate is reduced to arsenite by the action of the potassium iodide, the iodine being set free. The solution is then rinsed out in a large beaker and tenth-normal sodium thiosulphate added, drop by drop, to get rid of the iodine. On account of the dark color the end point is hard to read without practice. Tests are made from time to time with a drop of the solution on starch paste. After the operation is completed the solution is immediately made alkaline with solid sodium carbonate, again made slightly acid with hydrochloric acid and finally alkaline with sodium bicarbonate. Starch paste is now added and deci-normal iodine until the blue color appears. The figure thus obtained gives the total amount of arsenic present as arsenious oxid.

Methods are also given for determining the calcium oxid and the soluble arsenious and arsenic oxides in London purple.

Detection of coal-tar dyes in fruit products, A. L. WINTON (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 9, pp. 582-588).—The author mentions the increased use of coal-tar colors in the preparation of fruit jellies (frequently artificial), fruit preserves, soda-water sirups, etc. In the absence of special methods for detecting these, he has adapted a number of methods originally devised for wines. Working descriptions are given for Arata's wool test, the amyl alcohol tests (alkaline solution and acid solution), Girard's tests for acid fuchsin, and Cazeneuve's method, together with precautions which have been learned by experience.

The main reliance is based upon Arata's test, the other tests mentioned being employed either to confirm the results or to supply evidence in cases where that test fails. This is made by boiling 100 cc. of the liquid to be tested for 10 minutes with 10 cc. of 10 per cent potassium bisulphate and a piece of white wool or woollen cloth which has been previously heated to boiling in a very dilute solution of sodium hydrate, and thoroughly washed with water. If after washing the wool with boiling water and drying, it remains dyed and the color is not changed by ammonia, or if changed is restored by washing, coal-tar dyes, chiefly of the azo-group, are indicated.

The influence of carbon bisulphid and common salt on the losses of nutrients and the character of the fermentation of ensiled fodders, I. KALUGIN and S. PARASHCHUCK (*Zap. Noro-Alexandri Inst. Sel'sk. Khoz. i Lyosov.*, 1899, pp. 39; *abs. in Sel'sk. Khoz. i Lyosov.*, 196 (1900), *Fib.*, p. 470, 471).—The experiments were made with red clover, cabbage, and fodder carrots, which were stored in excavations in the ground. The close packing of the fodders was found to aid their preservation, the structure of the fodders being maintained and an agreeable odor produced; the loss of organic substances was reduced except that of proteids, whose decomposition was considerably increased. Close packing caused an increase in the formation of free organic acids. Loose packing, on the other hand, was not favorable to preservation, the structure of the fodder being lost, the fodders becoming covered with mold and acquiring a disagreeable odor, and the loss of organic substances increasing except in the case of proteids. The addition of carbon bisulphid contributes to a fine preservation of both closely and loosely packed fodders. Their structure is maintained and they acquire an agreeable honey-like odor after the carbon bisulphid has evaporated. The addition of carbon bisulphid considerably diminishes the loss of all organic nutritive substances, especially when the fodder is loosely packed, and arrests in a considerable measure the development of free organic acids.—P. FIREMAN.

On carnosin, a new organic base of meat extract, W. GULEWITSCH and S. AMIRADŽIBI (*Ber. Deut. Chem. Gesell.*, 33 (1900), No. 12, pp. 1902, 1903).

Qualitative test for boracic acid, E. W. and M. L. WADE (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 9, p. 619).—This depends upon the characteristic red color imparted to turmeric paper by the vapor resulting from boiling 0.1 gm. of the substance with 0.5 cc. of hydrochloric acid and 10 cc. of wood alcohol.

Paris green and London purple in Montana, F. W. TRAPHAGEN (*Montana Sta. Bul.* 25, pp. 7).—The author made analyses of 6 samples of Paris green and 2 samples of London purple bought of dealers in the State. It was found that arsenious oxid was present in Paris green in the proper proportion and nearly all in an insoluble form, the largest amount of soluble arsenious oxid in any sample being 1.29 per cent. Of the 2 samples of London purple which were analyzed 1 contained 50.89 per cent combined arsenious oxid, 0.54 per cent free, while the other contained 34.51 per cent arsenious oxid combined and 2.67 per cent free.

Estimation of fat in condensed milk, A. E. LEACH (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 9, pp. 589-591).—The author describes a modified form of the Babcock test for use where sugar has been added, which has proved not only much quicker than the method of extraction and easier of manipulation, but also more accurate. In this method the proteids are precipitated with copper sulphate solution and separated by whirling in a centrifuge, carrying down the fat also, and the supernatant liquid pipetted off. After washing the precipitated proteids and fat twice by shaking with water, the Babcock test is made as usual, the reading being multiplied by 1.8 to give the percentage of fat.

A rapid method for the detection of "aniline orange" in milk, H. C. LYTGOE (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 12, pp. 813, 814).—The name "aniline orange" is used to designate all azo-colors used in coloring milk. The use of these coloring matters in milk is found to be on the increase, and the following method is submitted for detecting them: To about 15 cc. of milk in a casserol, add an equal amount of hydrochloric acid (sp. gr. 1.20) and thoroughly mix, breaking up the curd into rather coarse lumps. If aniline orange is present, the curd will be colored pink.

A simple method for determining alum in wine, F. LOPRENTI (*Staz. Sper. Agr. Ital.*, 33 (1900), pp. 373-377; *abs. in Chem. Centbl.*, 1900, II, No. 24, p. 1216).—Alum is sometimes added to a poor wine to cover or to improve its character. To determine the presence of alum, concentrate 50 cc. of the wine to $\frac{1}{3}$ of its volume, decolorize with animal charcoal, neutralize the filtrate with sodium or potassium hydrate, make up to 50 cc., and test the solution with a drop of freshly prepared logwood. If the wine is free from alum the solution will be orange yellow; if alum is present the solution will be violet or blue.

Detection of foreign coloring matter in spirits, C. A. CRAMPTON and F. D. SIMONS (*Jour. Amer. Chem. Soc.*, 22 (1900), No. 12, pp. 810-813).—A method by the same authors has been previously noted (*E. S. R.*, 11, p. 312). The present method is found to be a much more satisfactory and convenient test. The 2 foreign substances used in coloring spirits are caramel and prune juice, and this method is based upon the insolubility of these coloring matters in ether. Details and tests of the method are given.

Determination of the acidity of flours, H. KREIS and C. ARAGON (*Jour. Suisse Chim. Pharm.*, 38 (1900), p. 64; *abs. in Bul. Assoc. Belge Chim.*, 14 (1900), No. 5, p. 232).

Recent studies on the solubility of lime in sugar solutions, J. WEISBERG (*Bul. Soc. Chim. Paris*, 3. ser., 23 (1900), No. 18-19, pp. 740-745; *abs. in Chem. News*, 82 (1900), No. 2142, pp. 284, 285).—Determinations of the solubility of lime in different forms at ordinary and at high temperatures are reported. Even at temperatures of 80 to 90° C. the solubility was considerable—much greater, in fact, than that found by Lamy.¹

Sixth annual report of the Michigan dairy and food commissioner (*Michigan State Dairy and Food Com. Rpt.* 1899, pp. 237).—This volume contains the commissioner's report and the usual statistics of inspections, analyses, and prosecutions under the State pure-food law, as well as a financial statement, report on cheese factories and creameries, and a digest of laws and opinions.

Report of the chemical division, B. C. ASTON (*New Zealand Dept. Agr. Rpt.*, 1900, pp. 127-137).—Complete or partial analyses were made of a number of samples of soils, waters, fertilizers, seed of *Chenopodium album*, sugar, crystallization preventive, vinegar, etc. Liquor obtained from a silo press was examined and found to contain 9.7 per cent of soluble albuminoids.

¹Sucr. Indig. et Coloniale, 11 (1876-77), p. 234-237.

BOTANY.

Recent investigations concerning the effect of perchlorates on the growth of crops, P. DE CALUWE (*Orgaan Ver. Oudleer. Rijks. Landbouwschool*, 12 (1900), No. 143, pp. 105-109, figs. 3).—During recent years it has been noted that grain fields, especially rye, are more or less seriously injured when fertilized with nitrate of soda containing perchlorates. The plants thus poisoned remain stunted; the leaves are short, stiff, and twisted, and the color is a very dark green. It has been a matter of dispute whether the injury was due to perchlorate of soda or of potash, though the evidence points to the former as the principal cause of the disease. The experiments carried on by the author in 1898 and 1899 demonstrated that sodium perchlorate is more injurious than potassium perchlorate.

For all of the experiments except one a field of rye that had been sown in the fall of 1898 was selected. This was cut up into plats and treated with sodium nitrate and with varying amounts of perchlorates of soda and of potash. There were (1) plats on which no fertilizer was used; (2) those to which only sodium nitrate was applied, and (3) those that received sodium perchlorate or potassium perchlorate without sodium nitrate. In the first series of experiments mixtures of 1, 2, and 3 per cent of the perchlorate and chlorate of potash with sodium nitrate were used. Check plats in each series received the equivalent of 2 per cent chlorate and perchlorate, but no nitrate of soda. The fertilizer was applied February 23, 1899, and in April the symptoms of perchlorate poisoning were clearly evident. The plats treated with chlorate did not show the symptoms of perchlorate poisoning, but the leaves were pale and etiolated in spots. The plats receiving chlorates and perchlorates, but no nitrate, showed very few symptoms of either the perchlorate or chlorate poisoning, although the growth was weak, owing to the absence of nitrates. The plats treated with sodium nitrate alone gave an increase of 31 to 33 per cent over the untreated plats, those to which chlorates as well as nitrate had been applied gave an increase of only 4 to 7 per cent, while on the 2 plats treated with perchlorates and nitrate there was a decrease in yield. The possible good effect of the nitrate was counteracted by chlorate and perchlorate, and the injurious effect of the latter was shown to be greater than that of the former.

The tests to determine the effects of sodium perchlorate were carried on at the same time and in a similar manner, except that twice as many plats were used and the percentages of perchlorates for the different plats varied from 0.75 to 2.6 per cent. Two plats were given perchlorate without nitrate. The injurious effects of the perchlorates were evident before the end of March. As compared with the plats treated with nitrate of soda alone the plats that received sodium per-

chlorate gave a decrease of from 3 to 50 per cent. Where only 0.75 per cent of perchlorate was used the poisonous effect was evident and the crop 3 per cent smaller than on the check plats. The plats treated with perchlorates without nitrates gave only half a crop, although the plants did not appear as badly injured as did those of some of the other plats. In November some plats were treated with sodium perchlorate, others with potassium perchlorate mixed with nitrates. The injurious effect was soon apparent, even when only 0.64 per cent of sodium perchlorate had been used, but in this case the plants eventually outgrew the effects of the poison. When 2 to 3 per cent of sodium perchlorate was used many of the plants were killed. The effect of the potassium perchlorate was ultimately outgrown, even when as much as 3 per cent of it had been mixed with nitrate of soda.

Experiments on turnips followed by rye showed that turnips are poisoned by perchlorates and that more than one crop may be injured by an application of nitrate of soda containing perchlorate. Oats and corn are also liable to injury, but do not suffer as seriously from it as rye.—H. M. PIETERS.

Electricity in plant culture (*Nature*, 61 (1900), No. 1590, p. 602).—A brief account is given of experiments conducted in Russia by Spyeshneff and Kravkoff. The former reported results of the well-known experiments with electrified seeds, in which he ascertained that such seeds germinated more rapidly and gave yields from 2 to 6½ times higher than seeds not subjected to the preliminary electrification. In another series of experiments copper and zinc plates were placed vertically in the soil and connected by wires. Potatoes and roots grown in the space between gave crops 3 times heavier than those grown in the test plat at the side.

In a third series of experiments by this author wooden posts were planted about 10 yards apart and provided at their tops with metal aigrettes connected by wires, so as to cultivate his plants under a network of wires. Among the most striking results obtained in this experiment was in the ripening of barley, which was accelerated 12 days.

The other investigator undertook a series of laboratory experiments upon bags of soil submitted to electric currents. The temperature of the soil was raised by these currents. Its moisture at first decreased, but afterwards increased to a considerable degree, and finally it is claimed the amount of vegetable matter in the soil was increased by the electric current.

On the embryo of mummy wheat and barley, E. GAIN (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 24, pp. 1643-1646).—An account is given of a number of investigations on specimens of wheat and barley which were taken from ancient tombs and are probably from 4,000 to 6,000 years old. Transverse and longitudinal sections were made of a large number of grains to ascertain what changes they had under-

gone. The author states that in order to have the seed germinate, it is necessary that the reserve material shall remain chemically unchanged, that the embryo shall preserve its structure, that an enzym be present for the reduction of the reserve material and that the embryo shall remain in contact with the reserve material for the proper transfer of the elaborated reserve material. Examination of a large number of specimens failed to show a single instance in which the embryo remained in contact with the reserve material. The embryo maintained its cellular structure, but had undergone very decided chemical changes. The scutellum and the rest of the embryo had become a reddish-brown color, and numerous microchemical reactions gave very different results for the embryos of the mummy cereals and those of more recent ones. The reserve material had apparently undergone no chemical change.

In conclusion it is stated that these mummy cereals, although externally in a fine state of preservation, did not possess the necessary organization for germination. Their reserve material had been chemically unchanged and was capable of utilization by a viable embryo, but the embryos in every case were so transformed as to be without the ability to grow. This chemical alteration seems to have taken place at a very remote period. It is the author's expectation to compare specimens of these mummy cereals with others less old to ascertain just what changes have taken place.

Injuries to plants by London fogs and smoke, G. HENSLOW (*Garden*, 57 (1900), No. 1487, pp. 353, 354).—An account is given of the injury caused by fog and smoke to plants, particularly in green-houses, in the vicinity of London. The most important and harmful ingredients of fog and smoke are said to be carbon, hydrocarbon derivatives, and sulphurous acid. One of the sources of injury is in the deposition of carbonaceous matter on the glass whereby the light is shut off. In similar ways the transpiration of the plant is largely affected, and both mechanical evaporation and transpiration are greatly impeded. The poisonous ingredients of fog are chiefly sulphurous acid and vaporized hydrocarbons which pass into the houses and injure the foliage of plants. The author says: "The amount of sulphurous acid has been found in analyses in dull weather in London to be ordinarily about 6 parts per cent (?), and in a thick yellow fog it amounts to about 20 per cent" (?). Artificial experiments with various amounts of sulphurous acid in water produced precisely the effect that was produced by the fog. The protoplasm of the plants was destroyed, a decomposition of chlorophyll grains and the formation of chlorophyllan taking place. Experiments with a number of hydrocarbon derivatives have shown similar effects, pyredin causing a rapid destruction of protoplasm, a limpness of the leaves, and subsequent browning. The action of these substances is usually first noticed upon the flowers. If the buds have expanded, the flowers become checked

and smaller, while if the injury takes place at a period just preceding the opening of the flowers, the flowers become yellow by the formation of chlorophyllan, and brown by the presence of tannins. In some cases buds are severely injured while expanded flowers are unaffected. In general, all flower buds opening during a fog perish.

Outlines of plant life, C. R. BARNES (*New York: Henry Holt & Co., 1900, pp. 308, figs. 250*).—An abridged edition of *Plant Life* by the same author (*E. S. R., 10, p. 416*).

Some native forage plants of the State, E. V. WILCOX (*Montana Sta. Bul. 22, pp. 54-56*).—Notes are given upon a number of indigenous forage plants which are valuable as forage or for hay. Among those mentioned are sagebrush, wild licorice, wild geranium, five-finger, lupines, and vetches. In addition, sweet clover is said to have been introduced and become quite abundant in a number of localities.

Some new species of the genus *Cratægus* and notes on some dichotomous *Panicums*, W. W. ASHE (*North Carolina Sta. Bul. 175, pp. 109-116*).—Descriptions are given of 21 new species of *Cratægus* and 7 new species of *Panicum*, belonging to what is known as the Dichotomous group.

The importance of the green leaf for the life of the plant, Z. KAMERLING (*Reprint from Arch. Java Suikerind. 1900, No. 5, pp. 20, pls. 3*).—A lecture delivered in which is presented the general subject of the rôle of chlorophyll in plant life.—H. M. P.

Flowers and fruits of common trees and shrubs, F. H. HILLMAN (*Nevada Sta. Bul. 46, Nature Studies 2, pp. 15, figs. 24*).—The general structures of flowers and fruits are described and the flowers and fruits of a number of the more common trees and shrubs are figured and discussed.

Nuclear phenomena in certain stages in the development of the smuts, R. A. HARPER (*Trans. Wisconsin Acad. Sci., Arts, and Letters, 12 (1900), pt. 2, pp. 475-497, pls. 2*).

The resin ducts and strengthening cells of *Abies* and *Picea*, H. B. DORNER (*Proc. Indiana Acad. Sci. 1899, pp. 116-129, figs. 11*).—Studies are reported on the structure of the leaves of the native species of fir and spruce, in which diagnostic characters are sought in the resin ducts and strengthening cells occurring in them.

Caoutchouc-yielding plants, P. VAN ROMBURGH (*Teyssmannia, 9 (1900), No. 7, pp. 342-345*).—The author mentions 4 species of *Urceola* as producing caoutchouc of good quality but in small quantity. *U. brachysepala* grows in 8 or 9 years to a height of 13 meters with a stem circumference of 30 cm. From 2 average plants of this species he obtained 50 gm. of caoutchouc. *U. javanica* is characterized by its large horn-shaped fruits, the weight of which is said to be so great that they sometimes break down the trees upon which the plant finds support. This is a serious objection to the cultivation of the plant. *U. elastica*, which grows to great size, and *U. maingajji* each yield small quantities of good caoutchouc.—H. M. P.

The influence of the assimilable nitrogen in the soil on the activity of the root tubercles of leguminous plants, BRUHNE (*Landw. Wechschr. Prov. Sachsen, 2 (1900), No. 46, p. 423*).—A brief article describing, in a popular manner, the results obtained by different investigators.

Influence of weather conditions on the root tubercles of leguminous plants, BRUHNE (*Landw. Wechschr. Prov. Sachsen, 2 (1900), No. 45, pp. 412, 413*).—These notes, based on the work of Nobbe and Hiltner, treat of the relation between the transpiration of the plant and the activity of the root tubercles of legumes. The author concludes from the results obtained by these investigators that leguminous plants for green manuring should be sown in season to allow them to develop sufficiently to insure activity of the root tubercles.

ZOOLOGY.

The food of the bobolinks, blackbirds, and grackles, F. E. L. BEAL (*U. S. Dept. Agr., Division of Biological Survey Bul. 13, pp. 77, figs. 6*).—In this bulletin the author discusses the food habits of the bobolink, cowbird, yellow-headed blackbird, red-winged blackbird, California red-winged blackbird, rusty blackbird, Brewer's blackbird, crow blackbird, and boat-tailed grackle.

It is stated that a study of the stomach contents of blackbirds confirms to some extent the popular estimate of their grain-eating habits, but shows also that these birds destroy large quantities of seeds of noxious weeds and a great number of insects. In general, it was found that the vegetable portion of the food exceeded the animal portion and that the latter consisted mainly of insects. The vegetable food comprised for the most part grain, grass, and weed seeds. The author states that the animal food of the 9 species of blackbirds must be considered for the most part in their favor, as the insects eaten are injurious.

Of bobolinks, 291 stomachs were examined, coming from 19 States and taken during 5 months from May to September. The food consisted of 57.1 per cent animal and 42.9 per cent vegetable matter. Most of the stomachs were collected in Northern States, but the author believes that the great damage done by bobolinks to the rice crops is due to the immense numbers of bobolinks and the fact that the rice fields lie in the direct course of their spring and fall migrations. It is concluded that the harm done by the bobolink far outweighs its benefits.

Of the cowbird, 544 stomachs were examined from 20 States, taken during every month of the year. The animal matter contained in these stomachs was 22.3 per cent, while the vegetable matter was 77.7 per cent. Corn, wheat, oats, and buckwheat were found in the stomachs, grain as a whole amounting to 16.5 per cent of the food of the year. Weed seeds amounted to 60 per cent of the whole food. The author summarizes the results of the investigation of this bird as follows: Twenty per cent of the cowbird's food consists of noxious insects; 16 per cent of grain, about half of which is waste grain; while more than 50 per cent consists of noxious weed seeds.

Of the yellow-headed blackbird, 138 stomachs were received from 10 States during 7 months. The food consisted of 33.7 per cent animal and 66.3 per cent vegetable matter. Grain, collectively, amounted to 38.9 per cent of the total food. While a considerable portion of this grain was undoubtedly waste, the bird may evidently do great damage to grain fields. The author concludes that this species feeds principally upon insects, grain, and weed seeds, that in general it does much good by destroying noxious insects and troublesome weeds, but that where grain is very abundant it may be injurious to such crops.

Of the red-winged blackbird, 1,088 stomachs were collected from 30

States during a whole year. The food consisted of 73.4 per cent vegetable and 26.6 per cent animal matter. Grain, collectively, amounted to 13.9 per cent of the food of the year, but it appeared that half of this was waste grain. Weed seed was apparently the favorite food of this bird, as the total amount of grass and weed seeds constituted 54.6 per cent of the year's food. The author concludes that judging by stomach contents the red-winged blackbird is a very useful bird.

Of the California red-winged blackbird, 61 stomachs were examined and of the total food 1.6 per cent was animal matter, while 98.4 per cent was vegetable matter and mostly grain. It would appear from these facts that this species may do great damage where it is abundant in grain-growing sections.

Of the rusty blackbird, 132 stomachs from 16 States were examined. The stomachs contained 53 per cent of animal matter. Corn was found to be the favorite grain food of this bird and constituted 17.6 per cent of the year's food. Grain, collectively, amounted to 24.4 per cent of the food for the year. The author believes from a study of this bird that the animal food is always preferred when available.

Of the Brewer's blackbird, 146 stomachs were examined from 6 States. The animal matter constituted 31.8 per cent and the vegetable matter 68.2 per cent of the food. Grain collectively amounted to 60.3 per cent of the total food for the year. Although this record is against Brewer's blackbird, the author states that comparatively few complaints have been received regarding the injuries of this species to grain fields.

Of the crow blackbird, 2,346 stomachs were examined, of which 37 contained traces of birds' eggs and 1 contained the bones of a young bird. The food as a whole comprised 30.3 per cent animal and 69.7 per cent vegetable matter. Insects constituted 27 per cent of the entire food for the year. Corn, oats, wheat, rye, and buckwheat were found in the stomachs of the crow blackbird, corn being evidently the grain preferred by this species. Among the large number of stomachs examined, 456 were of nestlings, the food of which consisted of 74.4 per cent animal and 25.6 per cent vegetable matter. Insects amounted to 70 per cent of the total food of the nestlings, while corn constituted 15 per cent of the total food. The author concludes from the examination of these stomach contents that the crow blackbird is a useful bird and one against which no general war of extermination should be waged.

Of the boat-tailed grackle, 116 stomachs taken in every month of the year were examined. The food comprised 39.8 per cent animal and 60.2 per cent vegetable matter. Grain constituted 46.8 per cent of the total food, and of this all but a mere trace was corn. The author concludes that wherever this grackle is abundant it may become very injurious to the corn crop.

In connection with nearly all the species discussed the author insists upon the fact that the feeding habits of blackbirds are during the greater portion of the year beneficial, and that the damage to grain crops is for the most part confined to limited seasons, and is especially noticeable where the birds congregate in great numbers.

Results of the biological reconnaissance of the Yukon River region, W. H. OSGOOD and L. B. BISHOP (*U. S. Dept. Agr., Division of Biological Survey, North American Fauna No. 19, pp. 100, pls. 7*).—This bulletin treats of the following subjects: Itinerary; a description of the faunal districts of the Yukon River region; a review of previous work done in this region; an annotated list of species and subspecies of mammals, some of which are described as new. The foregoing subjects are by W. H. Osgood while L. B. Bishop contributed an annotated list of the species of birds found in the region under discussion.

Scientific names in natural history, K. SAJO (*Prometheus, 11 (1900), Nos. 547, pp. 417-420; 548, pp. 433-437*).—The author criticises the habit of forming several specific names in the same genus which have the same significance, although possessed of a different form. The publication of specific descriptions in little known periodicals or those having a small circulation is also criticised. The author believes that this habit is partly responsible for the undue multiplication of synonyms.

The jackal plague (*Agr. Jour. Cape Good Hope, 17 (1900), No. 9, pp. 525-528*).—Brief notes on the extent of the depredations committed by jackals and foxes upon the sheep industry.

The value of birds to the commonwealth, F. M. CHAPMAN (*Connecticut State Bd. Agr. Rpt. 1899, pp. 76-113, figs. 30*).—Brief popular notes on the economic relations of a number of common species of birds.

A report on the family of bee-eaters (Meropidæ), K. A. SATUNIN and F. F. KAVRAISKI (*Trudi Karkaz. Schelkorod. Stutzii (Tiflis), 9 (1900), No. 2, pp. 33*).—The authors investigated the feeding habits of *Merops apiaster* and *M. persicus*, the 2 common European species of bee-eaters. Extended observations were made on these birds at the apiary connected with the sericultural station, and a report is made on the number of bees found in all the stomach contents which were examined, and upon other insects which were found to serve as the food of these birds. Observations are recorded from a number of correspondents in the different governments of Russia on the habits of the 2 species of birds in different localities. A map is given, showing the distribution of the birds in Russia.

Methods of destroying injurious animals, H. L. A. BLANCHON (*L'Art de détruire les animaux nuisibles. Paris: J. B. Baillière & Son, 1899, pp. 292, figs. 112*).—In this book the author has brought together and discussed in a summary manner the various methods which have been recommended for destroying noxious animals of all kinds. The volume contains a consideration of the following subjects: General methods of destruction and legislation against injurious animals; and special methods adapted for the destruction of injurious mammals, birds, reptiles, insects, crustacea, mollusks, and worms. Injurious insects are discussed under the headings of insects injurious to furniture, clothes and carpets, man and domestic animals, and field and garden crops.

Information concerning game: Seasons, shipment, and sale, T. S. PALMER and H. W. OLDS (*U. S. Dept. Agr., Division of Biological Survey Circ. 31, pp. 20*).—This circular contains a copy of the Lacey Act, a tabulated statement concerning the close seasons, the shipment of dead and live game, and the sale of game in the different States.

Wild animals and birds which may be imported without permits, J. WILSON (*U. S. Dept. Agr., Division of Biological Survey Circ. 30, p. 1*).—This circular contains a list of mammals, birds, and reptiles which may be imported freely without permits.

Laws regulating the transportation and sale of game, T. S. PALMER and H. W. OLDS (*U. S. Dept. Agr., Division of Biological Survey Bul. 14, pp. 89, pls. 9*).—This bulletin contains a compilation of the sections of various State laws which relate to the transportation and sale of game, and also tables and diagrams showing close seasons, species prohibited from shipment or sale, limits of game bags, and regulations concerning nonresident licenses.

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review, 28 (1900), Nos. 7, pp. 279-320, pls. 3, figs. 2, charts 8; 8, pp. 321-370, figs. 4, charts 8; 9, pp. 371-424, fig. 1, charts 13*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of July, August, and September, 1900, these numbers contain the following articles and notes:

No. 7, special contributions on Fog studies on Mount Tamalpais (illus.), by A. G. McAdie; Electric phenomena in the Euphrates Valley (illus.), by E. Huntington; Sudden disappearance of ice on the lakes, by H. H. Ten Broeck; Meteorological notes from Porto Rico, by R. M. Geddings; Forecasting for the farmer, by C. D. Reed; and Thunderstorms near Washington, by H. W. and H. S. Cragin; and notes by the editor on electric phenomena in the Euphrates Valley, notable lightning, the French edition of the Monthly Weather Review, Rafinesque on atmospheric dust, lightning from a cloudless sky, Weather Bureau station on Turks Island, wells and storms, the frequency and extent of destructive hail, atmospheric conditions favorable to cotton spinning, aurora in Florida, and progress in wireless telegraphy.

No. 8, special contributions on Nile floods and monsoon rains (*E. S. R., 12, p. 424*); Meteorological observations during the burning of the plant of the Standard Oil Company at Bayonne, N. J., July 5, 6, and 7, 1900, by W. H. Mitchell; Observations for local thunderstorms at Skyland, Page County, Va., August, 1900 (illus.), by H. W. and H. S. Cragin; Climatology of St. Kitts, W. I., by W. S. Alexander; and The hot weather of August, 1900 (illus.), by A. J. Henry; and notes by the editor on Weather Bureau men as instructors, monthly statement of average weather conditions, meteorological records in Ohio, climatological atlas of the Russian Empire, the influence of the Lakes on temperature of the land, and hydrography of Nicaragua.

No. 9, special contributions on Thunderstorms at Antigua, W. I., by W. H. Alexander; The storm waves of South Carolina and Texas, by E. P. Alexander; The Weather Bureau of Japan, by F. B. Wright; The color and the polarization of blue skylight, by N. E. Dorsey; Observations for local thunderstorms at Skyland, Page County, Va., September, 1900, by W. H. and H. S. Cragin; Meteorological observations at Eagle, Alaska, by A. J. Henry; Results of a balloon ascension at St. Petersburg, May 20-June 1, 1878, by M. Rykatcheff; The Gulf stream myth, by H. M. Watts; A review of Professor Very's memoir on atmospheric radiation, by N. E. Dorsey; and Monthly statement of average weather conditions for September, by E. B. Garriott; and notes by the editor on standard time, the frequency of hail in the United States, the crop as depending on meteorological conditions, and meteorological report from Nome, Alaska, September, 1900.

Report on the international cloud observations, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bureau Rpt. 1898-99, II, pp. 787, pl. 1, figs. 32, charts 73*).—This report gives the detailed results of cloud

observations in cooperation with the International Cloud Commission at 15 different places in the United States during the period from May 1, 1896, to July 1, 1897:

“In order to submit these results to a careful discussion, it has been necessary to prosecute a critical comparative study of several important theories heretofore proposed by meteorologists, so that the comparison between observations and theoretical computations can be suitably carried out. Accordingly, a standard mathematical system has been constructed, including in a definite notation the constants, the thermodynamic, and the hydrodynamic formulæ pertaining to the atmospheric physical processes and motions, by means of which the work of the several authorities can be reduced to one set of typical equations. The theories of the American and the German schools of meteorology have been contrasted, and the results derived from them have been compared with the facts obtained from these cloud observations. The grouping of the data secured by the theodolites and the nephoscopes has been so carried out as to make such a comparison simple and direct, the outcome being interpreted to mean that a modified theory of atmospheric motions is required to explain the local anticyclonic and cyclonic circulations, while the theory of the general cyclone, though partially sustained, also needs improvement in several important details. Furthermore, the thermodynamic processes have been submitted to a rigorous computation, especially in connection with cumulus clouds, by means of which the limits of the four standard stages, and the mean gradients of pressure, temperature, and vapor tension within each stage, have been carefully determined. The construction of this system of computation has put us in possession of a method of discussing several important fundamental characteristic features of the atmosphere, and it is evident that a continuation of research along these lines will not only tend to make of meteorology an exact science, but will also enable us to practically construct quite accurate daily weather maps at moderate elevations, that is, up to 1 and 2 miles above the surface. Such an outcome would amply repay the expenditure of much time and labor in the preliminary steps required to reach this goal; yet it is thought that the results contained in this report are such as to warrant the entering upon their actual application at once, with the expectation that further experience will merely improve upon the close approximations already secured.”

The author believes that increased equipment for observations of this character, including a permanent station for theodolite observations at Washington, D. C., and the equipment of each of the first-order stations of the Weather Bureau with a nephoscope will furnish the basis for a more accurate system of weather forecasting. To this end he recommends especially that the data collected be used in the construction of auxiliary maps showing the atmospheric motions at elevations of 3,500 and 10,000 ft.

Amount of chlorin in rain water collected at Cirencester, E. KINCH (*Jour. Chem. Soc. [London]*, 77 (1900), No. 457, pp. 1271-1273).—The total rainfall, and its content of chlorin, is given for each six months (October to March and April to September) from October 1, 1886, to September 30, 1900, together with averages for the winter and summer periods and for 14 and 26 years. The averages are as follows:

Rainfall and chlorin content of rain water at Cirencester, England.

	Rainfall, inches.	Chlorin, in parts per million.	Equivalent to NaCl, grains per gallon.	Equivalent to NaCl, lbs. per acre.
Mean of 14 winter periods to March, 1900.....	14.26	3.55	0.412	19.35
Mean of 14 summer periods to September, 1900.....	12.78	2.27	.261	10.40
Yearly average of 14 years to September, 1900.....	27.04	2.91	.337	29.75
Mean of 26 winter periods to March, 1900.....	15.83	3.76	.435	21.29
Mean of 26 summer periods to September, 1900.....	14.78	2.58	.302	14.81
Yearly average of 26 years, October 1, 1874, to Sep- tember 30, 1900.....	30.61	3.17	.369	36.10

"It will be seen that the total deposit of chlorids is distinctly greater in the winter months than in the summer months, this being largely dependent on the prevalence of S. W. gales from the Bristol Channel. . . .

"Taking all the chlorids as being in the form of sodium chlorid, the yearly average deposit of common salt per acre for the past 26 years has been 36 lbs., and for the past 14 years it has been nearly 30 lbs."

Rain, river, and evaporation observations in New South Wales, 1898, H. C. RUSSELL (*Dept. Public Ins., Met. New South Wales. Results of rain, river, and evaporation observations made in New South Wales during 1898. Sidney: Government, 1900, pp. 55+235, dms. 7*).—Rainfall and river observations at 1,581 stations, 1,517 of which are voluntary, are reported in detail. Readings of tide gages at 3 places are also reported. The average rainfall for the Colony during 1898 was 20.54 in., as against an average for 28 years of 24.85 in., being the fourth successive drought year. The rainfall increases notably with the location and elevation, the highest average rainfall recorded, 64 in., occurring just at the foot of a range of mountains 4,000 to 6,000 ft. high, against which the trade winds blow. Observations on evaporation from water surfaces at 10 places and also on wind movement at some of these places are recorded. The evaporators used are thus described:

"The vessels used are tanks 4 ft. in diameter and 3 ft. deep set into the ground 2 ft. 11 in., leaving 1 in. above the ground to prevent surface water running in. The float is of glass, and has a light brass tube extending upward through two guide holes. Above it is a screw gage so constructed that contact can be made with the top of the float rod, and the exact height of it to one-thousandth of an inch read off without a vernier. This is effected by having ten threads to the inch in the screw and the head working on it divided into 100, and therefore showing thousandths of an inch."

The total evaporation recorded during 1898 varied from 33.993 to 82.933 in. The mean temperature of the Colony for 1898 was 62.6° F. As regards long-range forecasts in New South Wales, the author states:

"I am fully convinced that a complete record of the rainfall will enable us to forecast the seasons with some show of success, provided, of course, that the extended knowledge of our rainfall is concurrent with a careful study of Australian and tropical weather, which is now in progress. . . . Further study will, there is reason to expect, explain the reason for dry years and when to expect them."

On the importance of aqueous vapor and carbon dioxid in their relation to absorption by the atmosphere, K. ÅNGSTRÖM (*Ann. Phys., 4. ser., 3 (1900), No. 12,*

pp. 720-732, figs. 4).—This is an account of apparatus used and results obtained in investigations similar to those recently reported by Very (E. S. R., 12, p. 723). Special attention is given to absorption by carbon dioxid. It was found that in no case did the absorption of terrestrial radiation by carbon dioxid exceed 15 per cent, and the amount of absorption varied very little with fluctuations in the carbon dioxid content, provided this was not less than 20 per cent. The principal result of a decrease of the carbon dioxid content is a somewhat wider diffusion of the radiated heat.

Climatological atlas of the Russian Empire (U. S. Dept. Agr., Weather Bureau, *Monthly Weather Review*, 28 (1900), No. 8, p. 343).—"As a memorial volume commemorating the fiftieth anniversary of the foundation of the Central Physical Observatory founded by the Emperor Nicholas I on April 1, 1849, the present director-general, M. Rykatcheff, has published a magnificent folio atlas, in which, by means of 89 meteorological charts and 15 graphical tables, he has presented the prominent features of the climate of the Russian Empire from Warsaw, on the extreme west, to Bering Strait, on the east, and from Teheran, on the south, to the Arctic Ocean, on the north."

British rainfall for 1899, H. S. WALLIS (*On the distribution of rain over the British Isles during the year 1899*. London: Edward Stanford, 1900, pp. 307, pl. 1, charts 4).—This, the fortieth volume of Symons's British Rainfall, gives a brief account of the life and work of G. J. Symons, the founder of the British rainfall service, who died March 10, 1900, and records data on rainfall collected by 3,500 observers. Besides the usual detailed records of the results of the year's observations, the volume contains a discussion of the average rainfall of the decade 1890-1899, as shown by observations at a hundred stations well distributed over England, Scotland, and Ireland.

Summary of weather at the North Louisiana Experiment Station during 1892-1899, J. G. LEE (*Louisiana Stas. Bul.* 62, 2. ser., pp. 473-477).—A monthly summary for each year of observations on temperature and precipitation.

Meteorological summary for 1899 (*Maryland Sta. Rpt.* 1900, p. IX).—A tabular monthly summary of observations at College Park, Md., on temperature and precipitation. The mean temperature for the year was 54° F.; the highest, 98°, June 7, the lowest, 4°, February 9. The total precipitation for the year was 45.8 in.

WATER—SOILS.

Principles of water analysis as applied to New Mexico waters, A. Goss (*New Mexico Bul.* 34, pp. 55-106).—This bulletin reports and discusses the results of analysis (sanitary and mineral) of 148 samples of stream, spring, and well waters examined in the laboratory of the station during the past 8 years. Analyses of 14 samples from sources outside of New Mexico are given for purposes of comparison. The bulletin includes the results of a continuation during 1899, in cooperation with this Office, of a study of the fertilizing value of the matter carried by the Rio Grande water, commenced in 1893 (E. S. R., 5, p. 1002), and of similar studies of the water of the Pecos River and other streams used for irrigation purposes in New Mexico.

"The total solids in the Pecos water are much higher than in the Rio Grande water, averaging in the 6 regular samples analyzed 314.20 parts as compared with 44.11 for the Rio Grande during 1893-94.¹ The alkali is also correspondingly higher in the

¹ The 3 samples of Rio Grande water analyzed in 1899 were from the small streams which came down the river after periods of complete dryness, and were therefore abnormally charged with alkali.

Pecos, averaging 157.38 parts as compared with 22.09 parts for the Rio Grande. The alkali in the Pecos water, like that in the Rio Grande, is all of the white variety. It is present, however, in such large amount that it would be very liable to cause trouble in a few years unless provision were made for draining the land and washing it out, or otherwise disposing of it.

"The sediment in the Pecos water is much less than in the Rio Grande, averaging but 179.6 parts in the former against 831.4 parts in the Rio Grande water even as taken from the ditch. This has a twofold bearing. In the first place, it is a disadvantage from the standpoint of plant food. On the other hand, it is an advantage from the standpoint of reservoir construction, as Pecos reservoirs should not fill up nearly so fast as Rio Grande reservoirs."

The practicability of pumping water for irrigation in the Rio Grande Valley is discussed. Nearly all the waters of this valley contain a large amount of lime. Water suitable for irrigation can generally be found, although the water is of better quality in the valley proper than at the edges of the same, where it is likely to be more highly charged with alkali.

"In the vicinity of Roswell, artesian water is found at a depth of from 200 to 300 ft. The water of these wells, so far as analyzed, runs from 88 to 121 parts total solids. This, while not so good as the water of the Rio Grande for irrigation, is very much better than the water of the Pecos, and when used with judgment should be safe, as the alkali present is all of the white variety. The considerable amounts of lime and magnesia present make the water very hard, and for laundry purposes it would give very much better results after being broken with soda."

The purification of water, especially the removal of lime and magnesia, K. SCHIERHOLZ (*Oesterr. Chem. Ztg.*, 3 (1900), No. 22, pp. 537-544).—Tests of the methods of adding lime and soda to correct hardness are reported. The addition of a slight excess of lime in the cold was effective not only in removing the lime and carbon dioxid, but also the magnesia except a trace. Soda removed both the free and combined lime, but was without influence on the magnesia. Methods of correcting hardness in waters containing sulphates of calcium and magnesium in addition to carbonates were also tested. The results indicate that such waters may be softened without the use of soda by adding lime to remove magnesia and carbon dioxid, barium oxid to remove sulphuric acid, and carbon dioxid or oxalic acid to remove the remaining free lime.

Water supply and sewerage (*Massachusetts State Bd. Health Rpt. 1900*, pp. 1-574).—This is a report to the legislature under provision of State laws, and includes advice to cities and towns regarding water supply, sewerage and sewage disposal, pollution of ponds and streams, ice supplies, and rules and regulations for sanitary protection of water supply; examination of water supplies; examination of rivers; summary of water supply statistics; experiments on the purification of sewage and water at the Lawrence experiment station in 1895, including report on tests of methods of sewage purification and filtration of water, the occurrence of iron in ground waters, and experiments on methods of removal (by H. W. Clark); and a report on

sewage purification of cities and towns in Massachusetts. The results of chemical and microscopical examinations of 212 different sources of water supply in use in various cities and towns of the State are given in this report. The experiments on the purification of sewage were devoted mainly to tests of rapid methods, especially the method of subjecting the sewage to decomposition and purification in a tank before applying it to a filter. The usual tables of water supply statistics are given, showing the number of towns supplied with water, the quantity of water used, and a summary of the records of rainfall and flow of streams.

Nitrification and catch crops, P. BONÂME (*Rap. An. Sta. Agron. [Mauritius]*, 1898-99, pp. 83-94).—Experiments in continuation of those of previous years (E. S. R., 9, p. 731) are reported. The following table gives the principal results obtained in a study of the progress of nitrification in a normal soil with or without the addition of nitrogenous fertilizers and lime (calcareous sand):

Amounts of nitric nitrogen per 100 gm. of dry soil.

	January 24.	February 12.	March 4.	May 20.	June 20.
Sulphate of ammonia (0.17 per cent nitrogen):	<i>Mg.</i>	<i>Mg.</i>	<i>Mg.</i>	<i>Mg.</i>	<i>Mg.</i>
Ordinary soil	7	17	27	34	41
Soil with 5 per cent of lime	8	46	66	120	140
Dried blood (0.17 per cent nitrogen):					
Ordinary soil	18	37	50	69	91
Soil with 5 per cent of lime	21	102	131	126	140
Fertilizer (0.17 per cent nitrogen):					
Ordinary soil	31	85	94	94	120
Soil with 5 per cent of lime	41	67	73	94	113
Normal soil without addition of any kind (0.3 per cent nitrogen).....	6	6.8	6.8	7	11

Experiments with calcareous sand of 3 grades of fineness indicate that up to 2 mm. in diameter the size of the grains is without effect on the rate of nitrification. Lime applied at one-fifth the rate of the sand was slightly more effective in promoting nitrification, Thomas slag standing next to the sand in this respect, and sulphate of potash third. Gypsum was practically without effect.

The rate of nitrification of some slowly nitrifying materials was tested with the following results:

Amounts of nitrogen per 100 gm. of dry soil.

	March 14.	April 17.	May 25.
Pea leaves:	<i>Mg.</i>	<i>Mg.</i>	<i>Mg.</i>
Without lime.....	11	22	24
With lime	20	37	43
Compost of cane leaves:			
Without lime.....	8	14	19
With lime	8	18	19
Manure compost:			
Without lime.....	10	16	24
With lime	11	19	25
Ordinary soil:			
Without lime.....	4	9	11
With lime	4	11	11

New researches into Pouillet's phenomenon (the heat developed in wetting powders), T. MARTINI (*Atti. R. Inst. Veneto*, 59, pt. 2, p. 615; *abs. in Phil. Mag. and Jour. Sci.*, 5. ser., 50 (1900), No. 307, pp. 618, 619).—Investigations are reported which show that there are certain substances, such as finely ground thermometer-glass, quartz, calcium carbonate, etc., which moisten well with water or other liquids, but which produce little or no heat under such treatment, while other substances, like powdered silica, the silicates, "vegetable earth," and "artificial coal," show decided rise in temperature when moistened with water, alcohol, ether, etc., the rise in temperature being greater the drier the powder. By carefully drying the materials the author obtained much higher figures for rise in temperature in silica and animal charcoal than were reported in a previous paper.¹ In the author's opinion the development of heat "is produced by the modification that the liquid undergoes when absorbed by the powder, by means of which modification the liquid is reduced to a condition of lower molecular energy." The experiments recorded are thus a contribution to the new theory of solid solutions. An application of this property of finely ground substances (*Benetzungswärme*) to the examination of soils has been noted (*E. S. R.*, 11, p. 1022).

Recent observations on the diluvial formation in the Netherlands with special reference to charting, II, H. VAN CAPPELLE (*Meded. Geol. Netherlands, Commissie Geol. Onderzoek*, 1900, No. 27, pp. 25, figs. 3, chart 1).—In this, the author's second paper on the subject, he discusses briefly the position of the moraine covering, of the sand, and of the loess formation in the Veluwe plateau in Gelderland. The moraine caps are infrequent and are sometimes covered with sand or gravel. Both the sand and gravel are of preglacial origin, and have evidently been washed down from the hills, of which there are many in this region.

The loess covers the tops of the hills, being thickest in the highest parts, and gradually mixed more with sand in the lower parts. This formation is extremely fertile and is known as the beechland because of the great development of beech trees on this soil. A stratified structure is apparent only when finer or coarser gravel has been mixed with the clay. The loess is closely related to the German Rhine-loess, and was laid down by the Rhine and the Yssel long before these streams had cut out their beds to the present level.

The author concludes that this deposit took place during the time that the second ice sheet approached the borders of the Netherlands and when also the Swiss glaciers spread far beyond their present boundaries.

There are two appendixes, in the first of which the physical structure of the Netherland loess is compared with other similar formations.

¹ *Phil. Mag. and Jour. Sci.*, 5. ser., 1899, No. 286, pp. 329, 330.

The author finds that in Gelderland, where the loess rests on preglacial sand and gravel, the loess contains a much larger amount of coarse sand than where it rests on a chalk formation, as in Limburg. In the second appendix are given the results of chemical analyses of 2 samples of loess.

The author gives a chart showing the location of the moraine caps in a portion of the Veluwe plateau.—H. M. PIETERS.

On the causes of the treeless conditions of the steppes, S. KRAVCOV (*Selsk. Khoz. i Lyessov.*, 196 (1900), Jan., pp. 1-13).—This article is essentially a criticism of the views of G. Tanfilyev relating to the causes of the treeless condition of the steppes, which are advocated by such authorities as A. N. Beketov and V. V. Dokouchayev. The résumé given of the views of Tanfilyev is as follows:

The geobotanical investigations of Tanfilyev have led him to the conclusion that chernozem (black earth) everywhere lies on rocks rich in lime and must be considered, from the nature of its vegetation, as belonging to the calcareous soils. The presence of lime in considerable quantity, as well as of an excess of common salt, is accompanied by the development of a peculiar vegetation. The difference in the vegetation of calcareous and noncalcareous soils can not be explained by the relation of these soils to humidity; nor are the heat properties of the soils of essential importance in this regard. Consequently the action of lime on the distribution of plants is chiefly chemical or due to its solubility in water. Tanfilyev concludes that the cause of the treeless condition of the steppes must be looked for in the character of the chemical composition of the chernozem. The fact that the latter lies everywhere on rocks rich in soluble salts, and especially in calcium carbonate, leads to the view that the treeless condition of the steppes is closely connected with the abundance of these salts in the soils of the steppes. Hence it follows that forests will be established only in localities where the conditions favor leaching of the soils, *i. e.*, on the slopes of ravines and on divides. In invading the steppes the forests descend from the divides along the declivities, advancing as the reduction of the soluble salts proceeds. Taking into consideration that chernozem lies everywhere on rocks rich in lime, and that the forest collects and holds the moisture which permeates the soil under it to a great depth, the author further infers that the forest soils must be leached out to a greater depth than those of the steppes. As an index of the degree to which this leaching has proceeded he selects calcium carbonate, which is always a constituent of the normal chernozem soils and subsoils and whose presence is easily detected by the addition of an acid. By the aid of the "method of effervescence" forest soils can be distinguished from those of the steppes.—P. FIREMAN.

FERTILIZERS.

The influence of the distribution of fertilizers on their action, J. M. POMORSKI (*Ztschr. Landw. Versuchsw. Oesterr.*, 3 (1900), No. 7, pp. 649-684, pls. 3).—Field and pot experiments with oats, barley, and celery are reported in which fertilizers (superphosphate, Thomas slag, nitrate of soda, sulphate of ammonia, and kainit) were applied (1) as top dressing, (2) in furrows and rows, (3) mixed with the whole of the surface soil, and (4) at different depths in the soil. The results show that the yield was influenced not only by the kind and amount but also by the distribution of fertilizers. The influence varies with the kind of plant and fertilizer and depends upon the character of the root system, the special fertilizer requirements of the plant, and the manner in which it takes up its food. It is therefore of great practical importance not only to determine the relative effectiveness of the different fertilizers for each soil, but also the method of application which will give the best results, taking into account at the same time the influence of supplementary fertilizers in modifying the action of the principal fertilizing ingredients required by the soil. It was found, for instance, in the experiments reported, that superphosphate in small amounts in the upper layers of the soil interfered with the action of nitrogen in sulphate of ammonia. In other words, the action of sulphate of ammonia was dependent upon the distribution of the other fertilizer in the soil. All fertilizers gave better results when mixed with the soil than when applied in layers.

Field experiments with phosphoric acid in various forms, F. W. DAFERT and O. REITMAIR (*Feldüngungsversuche über die Wirkung der Phosphorsäure in verschiedenen Formen. Vienna: Landwirthschaftlich-chemischen Versuchsstation, 1900, pp. 23*).—Field experiments with different samples of Thomas slag, superphosphate, Algerian phosphate, and degelatinized bone meal are reported. The phosphoric acid of Thomas slag, having a high citrate solubility, was no more effective on either summer or winter grain than that of slag having a low citrate solubility, the value of the slag being determined by its total phosphoric acid content. The purchase of slag on its citrate-solubility is condemned on both scientific and practical grounds. The degelatinized bone meal gave good results with summer grain. The author therefore concludes that the results of pot experiments which indicate that the phosphoric acid of bone meal is of no value are unreliable. Algerian phosphate appeared to be of equal value with Thomas slag for summer grain. The relative effectiveness of the phosphoric acid in Thomas slag and in superphosphate was as 70 to 100 in experiments with oats and barley. The effectiveness of the phosphoric acid in Algerian phosphate and bone meal was very nearly the same as that of the phosphoric acid of Thomas slag. The relative

value of the phosphoric acid in the various phosphates is calculated in this article from the increase in yield of grain. The author considers calculations based upon the recovery of the phosphoric acid in the crop to be entirely unreliable.

The action of burnt lime and marl on light sandy upland soils, NEUBERTH (*Deut. Landw. Presse*, 27 (1900), No. 79, p. 983).—These substances were compared on peas in 1896 on inoculated and uninoculated soils. The burnt lime did not interfere with the action of the inoculating soil. The yield was larger when lime was used in connection with inoculating soil than when marl was so used. When the lime and marl were used alone the yield was decidedly less with the former than with the latter, due especially, it is claimed, to the action of the lime in decomposing the organic nitrogenous matter of the soil and thus causing its loss by leaching, and also to volatilization of ammonia by the action of the lime. The nitrogen content of the crop grown with lime was much smaller than that of the crop grown with marl. The peas were followed by buckwheat in 1897 and rye in 1898 and 1899. No further applications of lime were made, but all plats received like amounts of stable manure each year. The effects of the liming were very marked on the last crop of rye. The crop was poorest on the unlimed soil and best on that which had received marl.

The results, it is stated, indicate the need of lime in such soil as that used in this test, but show that large applications of caustic lime may prove injurious. Marl seems to be better suited to soils of this character.

Analyses and valuations of fertilizers, L. A. VOORHEES and J. P. STREET (*New Jersey Stat. Bul.* 145, pp. 52).—This bulletin reports on the trade values of fertilizing constituents in 1900 and the results of examinations of the standard materials supplying them, as well as of home-mixed and factory-mixed fertilizers and miscellaneous fertilizing materials. The cost, valuation, and purchase of fertilizers, guaranteed and actual composition, and home mixtures and special fertilizers are discussed. Analyses and valuations are given of 47 samples of standard raw materials, 300 brands of complete fertilizers, 17 samples of home and special mixtures, 25 samples of ground bone and 31 samples of miscellaneous products. Materials examined included, in addition to the mixed fertilizers, nitrate of soda, sulphate of ammonia, dried blood, ammonite, dry ground fish, superphosphate, muriate of potash, sulphate of potash, kainit, wood ashes, licorice root ashes, land plaster, salt, marl, and muck. About 87 per cent of the brands of fertilizers examined contained as much total plant food as was claimed, but in only 71 per cent was the plant food distributed in the proportions stated. The averages for all brands of complete fertilizers examined during 1900 are as follows: Total nitrogen 2.41 per cent, total phosphoric acid 11.03 per cent (available phosphoric acid

8.44, insoluble 2.59), potash 5.89 per cent; station valuation \$20.77, selling price \$27.26.

From the data obtained "it appears that the manufacturers are delivering on the average practically the same amounts of total plant food as in 1899, in slightly different proportions, but at an average price per ton that is 49 cts. lower, notwithstanding the increase in the wholesale prices of ammoniates." The tendency noted in previous reports toward furnishing less nitrogen and more phosphoric acid and potash is still more marked in the average for 1900. The average cost per pound of nitrogen in 5 samples of nitrate of soda examined was 12.94 cts.; of 2 samples of sulphate of ammonia, 15.82 cts.; 3 samples of dried blood and ammonite, 14.17 cts.; 13 samples of ground fish, 13.66 cts. The average cost per pound of available phosphoric acid in 17 samples of superphosphate was 4.09 cts. The average cost per pound of potash in 5 samples of muriate of potash, 4.11 cts.; of 1 sample of sulphate of potash, 4.77 cts.; and 1 sample of kainit, 3.37 cts.

Nitrate of soda and sulphate of ammonia, R. WARINGTON (*Ann. Agron.*, 26 (1900), No. 11, pp. 530-561).—This is a translation from the English by E. Demoussy of an article which has already been noted in the Record (E. S. R., 12, p. 529).

Inspection and analyses of fertilizers, W. F. HAND ET AL. (*Mississippi Sta. Bul.* 64, pp. 31).—This bulletin contains brief statements regarding the collection of samples, the management of the fertilizer control during the season of 1899-1900, explanations of terms used in fertilizer analyses and of the valuation of fertilizers, suggestions regarding the form of certificate to be used on samples sent for examination and of guaranties to be used on packages of fertilizers, and tabulated analyses and valuations of 211 samples of fertilizers examined during the season of 1899-1900.

Another warning in regard to compost peddlers, W. A. WITHERS (*North Carolina Sta. Bul.* 173, pp. 83-90).—The purpose of this bulletin is to repeat a warning given in an earlier bulletin (E. S. R., 9, p. 123). This warning is emphasized by pointing out the defects in 2 fertilizer formulas which have been offered for sale in North Carolina. The bulletin also contains a list of books and other publications relating to fertilizers which the author recommends to those desiring information on this subject.

FIELD CROPS.

Field experiments, J. G. LEE (*Louisiana Stas. Bul.* 62, 2. ser., pp. 453-473).—Results secured in cultural and variety tests and in rotation experiments are here recorded. An account of the three-course rotation of corn, oats followed by cowpeas, and cotton has been previously noted (E. S. R., 7, p. 398). Data are here given for the crops grown during each of the years 1889 to 1899. A part of the experimental plats has been regularly manured. An examination of the results obtained shows that "the fertilized half has been built up 400 to 500 per cent in 11 years while that without fertilizer has gained from 12 to 25 per cent."

In a test of 27 varieties of cotton, the largest yield of seed cotton was afforded by Hawkins Prolific, closely followed by Texas Bur,

Truitt Improved, Jones Improved, and Hogerman. King was the earliest maturing variety.

Twelve varieties of wheat were grown on (1) deep red sandy soil and (2) light gray sandy soil. The tabulated results show an average yield for the 12 varieties of 22.08 bu. per acre on the red sandy soil and 12.26 bu. per acre on the light gray soil. The variety Eclipse, followed by Tuscan Island and Currell Prolific, gave the best yields on the red lands.

Of 27 varieties of corn tested, Mosby Prolific, Gondy Improved, and Cocke Prolific, with yields of 37, 36.7, and 31.9 bu. per acre, respectively, took the lead in productiveness. Shallow level cultivation gave the best results in culture experiments.

The value of irrigation water in addition to the natural rainfall was tested for sugar cane, corn, cotton, sorghum, tobacco, cowpeas, and watermelons. Equal areas for each crop were selected and $\frac{1}{2}$ of each area irrigated. It was assumed that the soil for sugar cane required for its best growth 25 per cent of moisture, corn 10 to 12 per cent, cotton and cowpeas 6 to 8 per cent, tobacco and sorghum 8 to 10 per cent, and watermelons 4 to 6 per cent. As nearly as possible these percentages of moisture were maintained for each crop by irrigation. The cowpeas did not mature pods in this experiment. The accompanying table shows the results per acre on the irrigated and unirrigated portions of the remaining plats:

Results of irrigation.

	Sugar cane.	Corn.	Sorghum.	Seed cotton.	Cured tobacco.	Water- melons.
	<i>Tons.</i>	<i>Bushels.</i>	<i>Tons.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Irrigated.....	11.50	20.85	3.42	1,892	1,204	18,834
Nonirrigated.....	3.44	10.44	1.98	1,548	751	9,632

The cane grown on the irrigated plat had a higher sugar content and percentage purity than that grown on the unirrigated. During the progress of the experiment it was found that the moisture content of 25 per cent was too high for the sugar cane on red sandy soil and the amount was therefore reduced to 14 to 16 per cent. It is believed that the difference in yields between the irrigated and unirrigated plats, as shown by the table, would have been more strikingly in favor of irrigation had fertilizers been used.

Experiments with bright leaf tobacco consisted of fertilizer and variety tests and a comparison of home-grown with Virginia-grown seed. In the fertilizer test the addition of nitrogen materially increased the yield. Phosphates and potash used either singly or combined gave but slightly increased yield over no manure. Sulphate of ammonia was not as effective as a source of nitrogen as cotton-seed meal, nitrate of soda, or dried blood. Virginia-grown tobacco seed with but 1

exception gave better results with 11 varieties of tobacco than home-grown tobacco seed.

Other data are included on the growth of sugar cane, cowpeas, forage crops, and grasses and clovers.

Results of fertilizer experiments with sulphate of ammonia, KLOEPFER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 10, pp. 376-384, figs. 3; 11, pp. 396-406, figs. 3; 12, pp. 436-445, figs. 2).—The results obtained in fertilizing potatoes, sugar beets, and fodder beets with different amounts of sulphate of ammonia are reported, the data being considered from the standpoints of yield and financial gain. With potatoes the best yields of 4 varieties tested and the largest financial gains were obtained with the variety Prof. Wohltmann, when 200 kg. of sulphate of ammonia was applied per hectare. The yield was at the rate of 26,384 lbs. per acre and gave a net profit of \$91.70. In the case of sugar beets, the largest yield of beets and tops was obtained by the application of 400 kg. of ammonium sulphate per hectare, but the greatest amount of sugar was obtained from the plat where only 300 kg. per hectare had been applied.

The varieties Tannenkrüger and Eckendorfer were used in the experiment with fodder beets. The greater yield was afforded by Tannenkrüger when ammonium sulphate was used at the rate of 400 kg. per hectare.

Fertilizer experiments with Thomas slag and nitrate of soda supplementary to barnyard manure, LILIENTHAL (*Fühling's Landw. Ztg.*, 49 (1900), No. 7, pp. 265-270, fig. 1, plan 1).—Experiments were made in supplementing liberal applications of barnyard manure for white cabbage, fodder beets, and a species of cabbage-turnip, with applications of 400 and 800 kg. of Thomas slag per hectare, of 200 kg. of nitrate of soda, and of a mixture of 200 kg. of nitrate of soda with 800 kg. of Thomas slag. The experiment was conducted on marsh soil, which proved detrimental to the best working of the nitrate of soda. Both the smaller and the larger applications of Thomas slag alone gave largely increased and financially profitable yields with each of the different crops grown. The use of 800 kg. of Thomas slag and 200 kg. of nitrate of soda, while giving slightly increased yields with fodder beets and cabbage turnips, was accompanied in each instance by financial loss. It is concluded from these experiments that supplementing the phosphoric acid of stable manure with Thomas slag is desirable.

Inoculation of soils, G. W. HERRICK (*Mississippi Sta. Bul.* 63, pp. 11, figs. 2).—In the experiments here recorded hairy vetch (*Vicia villosa*) was sown on 3 contiguous plats of soil at the station supposedly free from root tubercle germs. The first plat was inoculated with soil taken from an old field in which vetch had been previously grown. The inoculated dirt was scattered in the drills after the vetch had been

sown and both covered with soil. The second plat was used as a control. The third was sown with seed which had been treated with a water extract of infected soil. All plats were cultivated alike. Tubercles were especially abundant on the vetch roots in plat 1; they were less abundant on plat 3, and were but feebly developed in the control plat. The yield from the plat inoculated by scattering dry earth in the drills was 79 lbs., from the control plat 49 lbs., and from the plat inoculated with water extract 64.5 lbs.

Some general remarks on methods of inoculating soils, etc., are added.

Researches on the culture of blue lupines, P. P. DEHÉRAIN and E. DEMOUSSY (*Ann. Agron.*, 26 (1900), No. 4, pp. 169-196, figs. 2).—Pot and field culture experiments covering 3 years were made with blue lupines. The following are the more important conclusions based on the results obtained: Blue lupines will grow on either acid or alkaline soils. The presence of carbonate of lime in the soil is not an obstacle to their development. They are incapable of utilizing the gaseous nitrogen of the air without exterior aid. Blue lupines, like white lupines, often develop root nodules which are of little value in furnishing nitrogen to the plant. Lupines frequently thrive without there being nodules formed on their roots. Nitrogen in these cases may be furnished by the association of algæ and bacteria, which form organic material that may be directly assimilated by the plant. Neither the bacteria most favorable to the formation of useful root nodules on blue lupines nor the algæ and bacteria favorable to the formation of organic matter which can be taken up by the plants are widespread, a fact which often accounts for the poor growth of blue lupines in certain districts.

Varieties of cotton, E. R. LLOYD (*Mississippi Sta. Bul.* 62, pp. 8).—Twenty-four varieties of cotton were grown in 1899. Detailed data are given regarding the yield, value, and commercial classification of each. The 6 varieties giving the highest total money value per acre were Roby Prolific, Hawkins Jumbo, Smith Improved, Ozier Big Boll, King Improved, and Kemper Co. Cotton.

A summary of the results obtained in variety tests of cotton for each of the years 1889-1899 is included. This summary shows that the foreign varieties of cotton tested at the station have been of minor value. Long staple varieties of cottons when grown on hill lands have made smaller yields and given lower total values per acre than medium or short staple sorts. Varieties grown for a number of years on the northern border of the cotton belt mature earlier than when grown farther south. The yield and the length and value of the staple are greatly increased by the richness of the soil. This is said to be true especially of the long staple varieties. Further work at the station in variety testing is to be discontinued for the present.

Potato improvement and culture, M. FISCHER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 8, pp. 301-307, figs. 4; 9, pp. 343-352, figs. 6; 10, pp. 369-372).—Variations in the development of vines and tubers within the same variety, due to the form, size, or starch content of tubers used for mothers, were studied, as was also the ability of potato tubers to inherit and transmit individual characteristics. Similar work by the author has been previously noted (E. S. R., 10, p. 1039).

Tubers weighing between 60 and 70 gm. each were divided into 2 lots, the first of flat round tubers containing between 18.21 and 19.85 per cent of starch, and the other of long round tubers having only 11.83 to 13.79 per cent of starch, and these used for seed. Both the vine development and the yield of flat round potatoes were much less than that of the long round tubers. A comparison of 2 typical potatoes showed that if the yield of vines and tubers from the flat round potatoes be taken as 100, the weight of the vines from the long round tubers would be 142 and the weight of the tubers 216. Further experiments substantiated these results, and showed further that flat round potatoes high in starch content used for mothers produced a much larger proportion of tubers of a flat round form and having a high starch content than were obtained from planting long round potatoes low in starch content.

An explanation is given of the relation between form and starch content of potatoes. The zone richest in starch in potatoes lies next to the outside of the tuber. The inner part of the tuber is much poorer in starch. Other things being equal, the tuber having the greatest outer starch zone in proportion to the inner part or mark of the tuber will be richest in starch. The flat round potato should therefore contain more starch than the oblong form of equal weight, and this hypothesis is substantiated by analytical results. The matter of form is therefore considered of importance in selecting tubers for improvement on the basis of starch content. Considerable data are presented showing the relation of form of seed planted and product yielded.

In a comparison of nitrate of soda and ammonium sulphate, alone and in combination with superphosphate, as a fertilizer for potatoes, the best yields and greatest profits were obtained when the ammonium sulphate was used. Generally superphosphate was used at a loss.

Experiments were made in planting large potatoes, whole and cut in halves, in comparison with small potatoes. Large potatoes in both cases gave an increased yield over planting small tubers. After deducting the cost of the seed, the large potatoes cut in halves resulted in a loss and the large whole potatoes a gain over planting small tubers.

Lime experiments with potatoes on light marsh soil, LILIENTHAL (*Fühling's Landw. Ztg.*, 49 (1900), No. 12, pp. 459-462, fig. 1).—Two

varieties of potatoes were grown on light marsh soil poor in lime. Four plats were used in each test. Plat 1 was used as a check. The others received marl, loamy marl, and quicklime, respectively. Marl was used at the rate of 112 cwt. per hectare and quicklime at the rate of 54 cwt. per hectare. One of the varieties of potatoes grown, the Hamburger Egg potato, proved too tender for successful growth in the fresh marsh soil, and its culture resulted in decreased yields and financial loss except where ground marl was used. With the other variety of potato, the Bruce, increased yields were obtained with all the different forms of lime, but the greatest net profit with this variety, \$68.58 per hectare, was obtained on the plat given the ground marl. A table showing the amount of marl to apply on land when the marl contains different amounts of calcium carbonate is given.

Experiments in the culture of the sugar beet in Nebraska, H. H. NICHOLSON and T. L. LYON (*Nebraska Sta. Bul. 67, pp. 17-21, figs. 2*).—This bulletin summarizes the results secured during the season in cultural, fertilizer, and variety tests with sugar beets. As in previous trials (E. S. R., 11, p. 839), the experiments have been carried out on a large scale on the Standard Cattle Company's beet sugar fields at Ames, in the Platte River Valley.

Heavy clay soils have produced better beets both in years of average and of excessive rainfall than sandy loam soils, though they did not mature so rapidly. In selecting land for sugar beets the authors advise choosing a clay soil. Shallow cultivation 3 to 4 in. deep throughout the season, with the rows 18 in. apart and the plants 8 in. distant in the row, has again given the most satisfactory results. "A plan that gave very satisfactory results was to allow 18 in. between every fourth row and 15 in. between the others. This plan admits of horse cultivation if a four-row seeder and cultivator are used."

The author states that—

"Of the varieties tested during 1898 and 1899, on both heavy and light soil, the best were the original Kleinwanzlebener, Pioneer Kleinwanzlebener, Vilmorin, Drumez Elite, and Knauer. * * * The use of commercial fertilizers and of barnyard manure increased materially the yield per acre, but not the sugar content or purity of the beets. The advantage to be derived from the use of commercial fertilizers is not sufficient to pay for their cost. With barnyard manure, however, the case is entirely different, and its use either for a previous crop or directly for the beet crop is very profitable."

Experiments with wheat, 1900, F. C. BURTIS and J. G. KERR (*Oklahoma Sta. Bul. 47, pp. 26-48*).—Experiments are recorded consisting of early, medium, and late plowing; early, medium, and late seeding; growing wheat continuously on the same soil with and without manure, and tests of varieties.

In the first experiment, ground from which a crop of oats had been harvested was divided and sections plowed July 19, August 15, and September 11, respectively. The section plowed July 19 turned up

moist and mellow; that plowed August 15 turned up more or less dry and lumpy. Both these sections were harrowed at intervals after plowing until seeding time. The section plowed September 11 was weedy. It turned up lumpy, and was dry as far down as the plow ran. Rains which had greatly benefited the earlier plowed section were without measurable effect on this. Repeated disking, harrowing, and rolling was necessary to get it into any kind of shape. It is estimated that about 8 times the labor was put on it that would have been needed had the ground been moist at the time of plowing. All the sections were seeded September 15. The wheat in the earlier plowed section germinated promptly and continued to grow without check. On the late plowed sections many plants perished for want of moisture, and in the summer following the crop matured later, was more seriously affected by blight, and the grain was more shriveled. The yields from the different sections averaged as follows: Early plowed 31.32 bu., medium plowed 23.48 bu., and late plowed 15.3 bu. per acre.

"An important point to consider in connection with late plowing for wheat is the weeds on the ground, that help take its moisture and go to seed, making foul ground for future crops. Where this experiment was situated the soil was unusually free of weed seed, but some were present. On the August plowing the weeds were scattered and a part of them had gone to seed, but many of them were not matured. On the September plowing the weeds had gone to seed, but were not thick on the ground. Preventing weeds going to seed, and ridding the land of others that are started and destroyed by the frequent harrowings on early plowing, will well pay for an extra effort to do early plowing, to say nothing about the increase in yields of wheat that are obtained."

In the experiment to test the relative merits of early, medium, and late seeding, plats were seeded September 15, October 18, and November 15. The yields obtained from the different seedings were as follows: Early seeding 36.8 bu., medium 34.84 bu., and late 23.47 bu. per acre. The grain from the late seeding weighed 7 lbs. less per bushel than from the early or medium seeding. With late seeding, especially on poorly prepared land, about $\frac{1}{2}$ bu. seed per acre more than usual was required. In 6 former trials at this station the November seeding ranged in yields from 1 to 13 bu. per acre, the October seeding 4 to 30 bu., and the September seeding 15 to 49 bu.

Wheat has been grown continuously since 1892 on the same ground without manure. In 1898 one-half of the land was manured with barnyard manure at the rate of 15 tons per acre. The results obtained for the 2 seasons 1898-99 and 1899-1900 show yields of 30.6 and 36.8 bu. per acre, respectively, on the manured part, and 12 and 18.1 bu. per acre, respectively, on the unmanured.

Of 17 varieties of wheat grown in 1900 Sibley New Golden gave the largest yield, 44.5 bu., and Big English the smallest, 37.7 bu. per acre. The following varieties, most of which have been grown at the station for 6 years, are recommended: *Soft smooth wheats*.—Early Red

Clawson, Fultz, German Emperor. *Soft bearded wheats*.—Fulcaster, Missouri Blue Stem, New Red Wonder. *Hard smooth wheats*.—Red Russian, Oregon Red. *Hard bearded wheats*.—Sibley New Golden, Turkey Eversaw.

The moisture content of the plats plowed on different dates in these experiments was determined at various times from July 19 to May 14 following, and a record kept of the rainfall. On August 7 the plowed land had 5 per cent more moisture than the unplowed; on the 30th, the difference was 10.3 per cent. The moisture content of the unplowed land at this time was between 8 and 9 per cent, and the soil was too dry to plow readily. "September 11, three days before the date of seeding, the early plowed ground contained 16.8 per cent of moisture, the medium plowed 13.9, and the late plowed only 7.7 per cent—4.3 per cent less than the amount required to germinate wheat readily, while the early plowed contained 4.8 more than the required amount." Manured land did not seem to retain any more moisture in these experiments than unmanured.

Field experiments with wheat, J. F. HICKMAN (*Ohio Sta. Bul. 118, pp. 213-238*).—The variety and cultural experiments with wheat begun by the station in 1893 and reported on up to 1897 (E. S. R., 9, p. 1046) have been continued and are here reported in detail for 1899 and averaged for the whole period. At the station farm Poole, Mealy, Red Russian, and Early Ripe of the smooth varieties, and Nigger, Currell Prolific, Gypsy, and Egyptian of the bearded varieties have given the highest yields. The variety Valley seems especially adapted to rich alluvial soils. For upland soils Poole, Mealy, Red Russian, Nigger, and Improved Poole are recommended. "In a single experiment conducted on good clay land in Cayuhoga County, the Velvet Chaff wheat gave better results than any other of the 10 under test."

So far as the station's observations have gone, no variety of wheat has been found fly proof, but Mealy, Mediterranean, Fulcaster, and Clawson are among the sorts considered most resistant to the Hessian fly. Replies to a circular of inquiry regarding the resistance of the Mealy variety of wheat to the Hessian fly are included in the bulletin.

The range in date of ripening of the different varieties of wheat tested has rarely exceeded 12 days. The conclusions reaching regarding the various cultural features under test are as follows:

"Higher average yields have been produced where the quantity of seed used reached 9 and 10 pk. per acre on moderately productive clay soil.

"Wheat grown upon ground sufficiently seeded to produce the highest yield per acre has given highest average weight per measured bushel. The lightest weight wheat has been grown where land was seeded more lightly.

"Better results have been secured by seeding in this latitude from the 12th to the 20th of September than by earlier or later seeding.

"Wheat one year old, if it has been kept in a suitable place and is of fair quality, will likely be as good to use for seed as new wheat.

"Spring wheat, with present condition of Ohio soils and climate, is not likely to prove successful. After repeated trials on rich, alluvial land and upon the thinner clay land our experiments have proved failures, both in quantity and quality of wheat produced."

Report of the agriculturist, E. R. LLOYD (*Mississippi Sta. Rpt. 1900, pp. 15-19*).—A report of variety tests with cotton (see p. 844) and wheat, fertilizer experiments with cowpeas, and culture experiments with sorghum, cowpeas, and corn. Sorghum drilled alone and cut after the heads had nearly ripened yielded 10,333 lbs. of cured hay per acre. When drilled with cowpeas the total yield of cured hay was 7,250 lbs. per acre. Sown broadcast together the yield was 8,207 lbs. per acre. The greatest yield of grain was obtained when corn was allowed to ripen on the standing stalk.

Report of the assistant agriculturist, R. S. SHAW (*Montana Sta. Bul. 24, pp. 145-150*).—Outline of the work of the year with the tabulated yields, etc., of 66 varieties of wheat, 44 of oats, and 21 of barley.

Report on farm work at the Momohaki, New Zealand, Experiment Station, F. GILLANDERS (*New Zealand Dept. Agr. Rpt. 1900, pp. 231-247*).—This report briefly describes the manner of carrying on the work and gives the results obtained in tabular form. The experiments comprise variety tests with cereals, grasses, potatoes, and root crops, and a fertilizer test on mangel-wurzels.

Deep-rooted plants for green manuring (*Hessische Landw. Ztschr., 70 (1900), No. 48, pp. 664, 665*).—A popular article referring to results obtained by different investigators of the subject.

Fenugreek (*Trigonella phœnum græcum*) as a soil improver, G. D'ANCONA (*Staz. Sper. Agr. Ital., 33 (1900), No. 4, pp. 357-364*).

Grasses for permanent meadows on marshy soils, C. NISSEN (*Landw. Wechnbl. Schleswig-Holstein, 50 (1900), No. 48, p. 827*).—Brief notes on a number of desirable and undesirable grasses for this purpose.

Grasses for pastures and meadows, TANCÉ (*Landw. Wechnbl. Schleswig-Holstein, 50 (1900), No. 51, pp. 869-872*).—The value of different grasses for these purposes is discussed and various grass mixtures suggested.

Historical notes on hop culture in the Altmark, BRÜHNE (*Landw. Wechnschr. Prov. Sachsen, 2 (1900), No. 45, pp. 411, 412*).—Popular historical notes on hop culture in the region of the Province of Saxony known as the Altmark.

Experiments with potatoes, A. JÄGER (*Deut. Landw. Presse, 27 (1900), No. 96, pp. 1155, 1156*).—Results of variety tests for the years 1898 to 1900.

Potash for potatoes (*Agr. Jour. Cape Good Hope, 17 (1900), No. 11, p. 665*).—A popular article on the need of potash in the soil for the successful growth of the potato.

Special potato trials (*New Zealand Dept. Agr. Rpt. 1900, pp. 255-263*).—A report on a test of 111 varieties of potatoes grown at Waihao and Wyndham. The results are given in tabular form. Among the best yielding varieties were Dalmahoy, White Rock, Carter Abundance, and Durwent, with yields of over 11, 10, 9, and 8 tons per acre, respectively.

Does nitrogenous manuring of sugar seed beets have an injurious effect on the succeeding progeny? H. WILFARTH (*Bl. Zuckerrübenbau, 7 (1900), No. 7, pp. 105-110*).—A review of the literature on this subject does not show that this common practice is harmful.

The recent practice of disregarding the established laws in sugar-beet culture and its injurious effects (*Bl. Zuckerrübenbau, 7 (1900), No. 23, pp. 362-367*).—This article is an extract from a lecture on the subject and treats of the manner and time of plowing for sugar beets, the distance at which the beets should be planted, and when and how the thinning should be done.

The daily root work of sugar cane (*Rev. Agr. Réunion, 6 (1900), No. 10, pp. 431-440*).—The discussion of the subject in this article is based on the results of an investigation of the composition of sugar cane by J. D. Kobus, Director of the West Java Experiment Station.

Tobacco culture and industry, E. BOUANT (*Culture et industrie du tabac. Paris: J. B. Baillière & Son, pp. XII+347, figs. 104*).—The culture, technology, economic importance to the State, and the use of tobacco from a hygienic standpoint are considered in this work. Under culture, chapters are given on statistics, soils and manures, harvesting, and enemies of tobacco; and under technology, chapters on the manufacture of cigars, snuff, chewing tobacco, and secondary products.

Report of wheat raisers, J. FIELDS (*Oklahoma Sta. Bul. 47, pp. 3-25*).—Letters of inquiry requesting information regarding wheat farming were sent out by the station to farmers in the Territory, to which 118 replies, representing 18 counties, were received. These are summarized. They indicate that the soil for wheat in Oklahoma should be plowed early and deep and well worked before seeding. The seeding should be complete before October 15. Pasturing vigorously growing wheat in the fall has been found profitable by many farmers. Grading up seed wheat by the use of a fanning mill is regarded as profitable. Losses from insect ravages have been slight, but rust has frequently affected late wheat. "Hard wheats as a rule are preferred in the western counties and on the uplands. Soft wheats are grown in the eastern counties. Rotation is generally preferred to continuous culture for wheat, and the beneficial effect of manure is mentioned in many cases."

Culture experiments with different square-head varieties of wheat, EDLER (*Landw. Ztschr. Rheinprovinz, 1 (1900), No. 24, pp. 277-279*).—A brief review of the different experiments in this line from 1895 to 1899, inclusive.

The value of varieties of grain with a low stooling quality for breeding purposes (*Deut. Landw. Presse, 27 (1900), No. 101, p. 1207*).—A discussion of results obtained by Schribaux.

HORTICULTURE.

Cabbage—fertilizers, varieties, shipping; cauliflower—varieties and shipping, B. C. PITTUCK and S. A. McHENRY (*Texas Sta. Bul. 57, pp. 24, figs. 14*).—General directions are given for growing and marketing cabbage and cauliflower, including a financial statement of the sale of a carload of cabbage shipped by the station to Kansas City, and an estimate of the cost of growing an acre of cabbage. This is placed at \$12.85. Resin-lime mixture has been one of the most effective remedies used against the cabbage worm, and seemed to drive the harlequin bugs away from the plants for a few days. The hot blast blow torch was used successfully for killing both bugs and worms.

In the variety tests with cabbage, Stein Early Flat Dutch gave the largest yield per acre, 28,984 lbs., followed by Autumn King and Frotcher Superior Large Late Flat Dutch, with a yield of 25,935 and 25,810 lbs. per acre, respectively. The experience of the station, coupled with previous observations, show that Danish Ball Head will not withstand a greater degree of cold when the plants are young than the average variety. If the heads are two-thirds grown they stand more cold than any other variety tested. "For extreme hardiness in all stages of growth Frotcher Superior Large Late Flat Dutch has proven better than any other variety."

The coldest weather at the station generally comes between February 15-25. By planting early maturing varieties about August 1 and forcing growth by the liberal use of fertilizers, it is thought the crop may be matured before the February freeze occurs. The 2 varieties, Early Jersey Wakefield and Frotscher Superior Large Late Flat Dutch, were used in testing the relative merits of commercial fertilizers, barnyard manures, and ashes for cabbage. The effects of the barnyard manure were noticed about 2 weeks after it had been applied, while the commercial fertilizers produced no noticeable effect on the growth of the plants until about 6 weeks after the date of application. With the fertilizers and combinations used with both varieties of cabbage, the best and cheapest yields were obtained from the plat fertilized with stable manure at the rate of 20,000 lbs. per acre.

The experiment in growing cauliflower was practically a failure, owing to the damage to the crop by cold and the failure to apply manures. This crop is considered, however, a profitable one to grow, but heavy manuring, as with cabbage, is considered essential to success. The methods of culture employed and the results obtained in a test of 5 varieties are recorded. "Early Snowball proved to be the surest header and earliest variety in the test." Late Italian Giant was a good variety.

The use of chemical manures on garden vegetables, G. TRUFFAUT and DENAIEFFE (*Jour. Soc. Nat. Hort. France*, 4. ser., 1 (1900), Dec., pp. 868-877).—The authors conducted experiments with fertilizers on vegetables, using theoretical formulas based on the analyses of the vegetables. Preliminary to the experimental work, a large number of vegetables were grown and analyzed when they had reached their maximum development, and a part of these data are reported. Tests were conducted in 1898 and 1899, different vegetables being fertilized with large amounts of fertilizers compounded as noted above. The soil used was rich in organic nitrogen and lime, but relatively poor in potash and phosphoric acid. Based upon the results obtained the authors have prepared the following general fertilizer formulas for different sorts of vegetables:

For beets, cucumbers, carrots, radishes, parsnips, turnips, salsify, potatoes, pumpkins, and squashes, a fertilizer containing 8.3 per cent nitrogen, 11.5 per cent potash, and 14.1 per cent phosphoric acid; for garlic, shallots, onions, leeks, and chives, a fertilizer containing 5.65 per cent nitrogen, 20.1 per cent potash, and 10.35 per cent phosphoric acid; for eggplants, peppers, and tomatoes, a fertilizer containing 7.65 per cent nitrogen, 17.2 per cent potash, and 11.2 per cent phosphoric acid; for cabbage, lettuce, corn salad, sorrel, spinach, artichokes, cardoon, asparagus, celery, and white beets, a fertilizer containing 9.65 per cent nitrogen, 5.95 per cent potash, and 13.45 per cent phosphoric acid; and for strawberries, beans, lentils, and peas, a fertilizer containing 4.05 per cent nitrogen, 8.2 per cent potash, and 17.5 per cent phosphoric acid.

Top-working apple trees, G. H. POWELL (*Delaware Sta. Bul.* 48, pp. 16, figs. 12).—A popular discussion of the methods and advantages of top-working apple trees. Using a hardy, vigorous, straight-growing variety as a stock on which to top-work the permanent orchard, the advantages of the method are summarized as follows:

"It provides a healthy, strong trunk for all varieties, corrects the poor growth of some, overcomes the tenderness of others in the far north, and sometimes makes a stronger system of roots. It gives the grower a chance to select the buds or scions from trees of steady productiveness, hardy foliage, and highly colored fruit. It is said to hasten fruitfulness.

"The stock should be of a vigorous-growing variety as free as possible from body troubles. The Spy makes an ideal stock, and the Ben Davis, Baldwin, Lily of Kent, Tallman Sweet, and Astrachan are in use. Seedling stocks are undesirable, as no 2 of them are alike. . . . Body budding seems to be the most desirable method."

Experiments on the use of nitrate of soda in the culture of grapes, E. MARRE (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 50, pp. 716-720).—Nitrate of soda was used in the culture of a number of varieties of grapes on different soils. The average increase in the yield of the nitrate over control plats was a little more than 23 per cent. The conclusions of the author are practically as follows: Nitrate of soda, whether used alone or combined with barnyard manure or commercial fertilizers, always increased the yield at a profit. Dry weather diminished the beneficial action of nitrate of soda, which was most effective after rains. Applying nitrate at 2 different times and working it into the soil seemed to give the best results. The nitrate was most effective in the presence of phosphatic manures.

Experiments with manures on vines, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 51, pp. 753-760).—The value of nitrate of soda in addition to phosphoric acid and potash for vines was determined in plat experiments in 3 different localities. The fertilizers were applied between the rows and worked in. The addition of the nitrogen to the phosphoric acid and potash greatly increased the yields in every instance, besides hastening the maturity of the fruit and improving its quality. It is believed that this effect will be best obtained when the potash and phosphoric acid are applied broadcast between the rows in December or January, and the nitrate of soda in March or April, and thoroughly worked into the soil.

The herbaceous vine graft, TRABUT (*Bul. Agr. Algérie et Tunisie*, 6 (1900), No. 11, pp. 307, 308, fig. 1).—Budding in August and the English or Lafleur method of herbaceous grafting are described.

Crossing and hybridizing, F. DORNER (*Amer. Florist*, 16 (1900), No. 657, pp. 752, 753).—Paper read by the author before a late meeting of the Indiana Horticultural Society.

New food yam, *Dioscorea fargesii*, D. BOIS (*Rev. Hort.* 72 (1900), No. 24, pp. 684, 685, fig 1).—This yam, which has been grown to a limited extent in private gardens, is described. The vine is hardy. The tubers are spherical and rather small,

develop at a shallow depth, are easily harvested and of good quality, though inferior in this latter respect to *Dioscorea batatas*.

The "cheyote," *Sechium edule*, L. TRABUT (*Bul. Agr. Algérie et Tunisie*, 6 (1900), No. 22, pp. 617-622, fig. 1).—Directions for the culture and uses of the cheyote, or vegetable pear.

Report of the horticulturist, S. M. EMERY (*Montana Sta. Bul.* 24, pp. 125-144).—An outline is given of the work of the year with orchard fruits and strawberries. Lists are given of the apples, pears, crabs, cherries, apricots, prunes, and plums set in the orchard and the number alive after the severe winter of 1898-99.

A test was made of the value of root-pruning two-year-old apple trees according to the Stringfellow method, as compared with those treated normally. Out of 20 trees root-pruned according to the Stringfellow method 12 failed to come out alive in the spring of 1899, while out of 80 unpruned trees only 24 failed to come through the winter. It is stated in this connection that the winter of 1898-99 was the most severe in the history of the station and that of the 20 root-pruned trees only 4 could be classed as especially hardy. The results are considered so favorable that further experiments along this line will be undertaken.

The report on strawberries covers the tabulated data secured in a test with 61 varieties.

The content of plant nutrients in apples and pears, E. HOTTER (*Ztschr. Landw. Versuchsw. Oesterr.*, 3 (1900), pp. 533-585; *abs. in Ztschr. Untersuch. Nahr. u. Genussmit.*, 3 (1900), No. 12, p. 833).—The average composition of the ash of 20 varieties of apples and 13 varieties of pears is recorded. The apples were slightly richer in total ash and nitrogen than the pears, but contained only about half as much sulphuric acid. Otherwise the composition of the two was very similar.

Plum in Kansas, with a chapter on prunes (*Topeka: State*, 1900, pp. 159).—This consists of a large number of articles compiled from horticultural journals, bulletins, and reports, by W. H. Barnes for the Kansas State Horticultural Society. The work also contains reports of many Kansas plum growers. The articles selected treat of the botany, pollination, culture, varieties, insects, and diseases of plums, etc. The chapter on prunes is taken largely from California and Oregon sources. It is not expected that prunes can be grown with profit in Kansas, but it is thought that there is a large opening for the plum industry.

California navel lemon (*California Cult.*, 15 (1900), No. 26, p. 402, fig. 1).—The origination of an absolute seedless lemon is reported. Illustrations of the new lemon and of cross sections are given.

Olive culture, W. J. ALLEN (*Agr. Gaz. New South Wales*, 11 (1900), Nos. 10, pp. 829-836, pls. 5, figs. 5; 11, pp. 1020-1022, figs. 4; 12, pp. 1059-1074, pls. 11, figs. 4).—Popular article dealing with the history and propagation of olives, soils, transplanting, cultivation, pruning, varieties, oil making, pickling, etc. In the Wagga olive orchard the varieties Bouquettier and Correggiola have been found superior to all other varieties in the production of oil, and these are recommended for planting.

Fruit tree culture in pots, J. HUDSON (*Garden*, 58 (1900), No. 1507, pp. 264, 265, figs. 2).—Fruit houses, potting and pruning trees, and varieties of peaches, plums, cherries, pears, and apples best suited for growing in pots are noted.

Forcing fruits under glass, W. TURNER (*Amer. Gard.*, 22 (1901), No. 318, p. 58).—Forcing in borders and in pots is considered and a list given of early, midseason, and late varieties of peaches, nectarines, pears, plums, apples, and figs suitable for the purpose. The temperature at which the house should be held at different periods in the growth of the fruit, methods of watering, pruning, etc., are also considered.

The cocoa tree; its culture and management in all countries of production, H. JUMELLE (*Le cacaoyer; sa culture et son exploitation dans tous les pays de production*. Paris: Augustin Challamel, 1900, pp. 211, figs. 19).—A comprehensive treatise on the

botany, chemistry, commerce, culture, and the insects and diseases of the cocoa tree and its products; and on the countries which produce cocoa. The work is prefaced by a brief historical discussion pertinent to the subject.

The manuring of coffee, A. LEHMAN (*Planting Opinion*, 5 (1900), No. 47, pp. 796-799).—A lecture on the subject, with suggestions regarding experiments.

Coffee, its preparation and effects, GOODFELLOW (*Planting Opinion*, 5 (1900), No. 48, pp. 821, 822).—A popular article, giving statistics on the production and consumption of coffee, and discussing the constituents of the properly prepared article and the methods of its preparation.

Tests of small fruit, J. TROOP (*Indiana Sta. Bul.* 83, pp. 107-114).—Data are here recorded for tests of 82 varieties of strawberries, 32 raspberries, 18 blackberries, and 1 dewberry, in continuation of work previously reported with these fruits (E. S. R., 10, p. 1042). Of the raspberries grown Miller, Cuthbert, Columbian, Golden Queen, Alpha, Conrath, Eureka, Kansas, and Nemaha are recommended for both market and home use. Subsoiling for raspberries is advised. Lucretia is the only dewberry recommended for general cultivation. Of the blackberries grown Agawam, Early King, Erie, Snyder, and Taylor are considered the best for the family garden.

Strawberries, F. S. EARLE (*Alabama College Sta. Bul.* 109, pp. 39-51).—Descriptive notes and cultural data are given on 34 varieties grown at the station, and suggestions given regarding the establishment of a strawberry plantation. Earlier work with strawberries at this station has been recorded in E. S. R., 10, p. 552.

Strawberry culture, E. HECHLER (*Der Erdbeerfreund*. Erfurt: J. Frohberger, 1898, pp. 126, figs. 14).—Practical directions for the culture and rational use of different varieties of strawberries for domestic use and the trade. Some 40 recipes are given for utilizing the fruit.

Resistance of strawberries to frost, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 17-21).—Preliminary work on this subject has been previously reported (E. S. R., 11, p. 247). In the author's further investigation it has been found that with those varieties of strawberries in which injury from frost was greatest, "the seeds were most exposed or were situated in very shallow depressions of the strawberry pulp. On the other hand, in those varieties which did not suffer from frost, the seeds were protected by being embedded so deeply in pits of the plant that they were practically surrounded by the pulp. Between these 2 extremes there was found a regular series of graduations represented by varieties in which the seeds were embedded in pits in the pulp of varying depth."

Viticulture and wine making in Algeria, J. BERTRAND (*Bul. Agr. Algérie et Tunisie* 6 (1900), Nos. 9, pp. 223-253, figs. 6; 10, pp. 265-301, fig. 1).—A general article covering soils, varieties, manure, culture, diseases, etc., and the manufacture, storage, and commerce of wine. One part is devoted to the phylloxera and the reconstruction of vineyards. The financial aspect is also considered.

Culture of caoutchouc in Brazil, L. FURQUIM D'ALMEIDA (*De l'exploitation du caoutchouc au Brésil*. Brussels: Oscar Schepeus & Co., 1900, pp. 24).—Countries and plants which produce caoutchouc and methods of cultivating, harvesting, extracting, and preparing for market are considered.

Grafting experiments with Malvaceæ, H. LIMLEMUTH (*Gartenflora*, 50 (1901), No. 1, pp. 8-11).—*Malvastrum capense* and *Lavatera arborea* were grafted on *Abutilon thompsoni*. In both instances the scions grew rapidly and bore yellow variegated leaves. Cuttings from the scions were made, some of which the author succeeded in rooting. These also produced the characteristic yellow variegated leaves of *Abutilon thompsoni*.

A new clematis with fragrant flowers, D. BOIS (*Jour. Soc. Nat. Hort. France*, 4. ser. (1900), Dec., pp. 865-868, fig. 1).—The author describes *Clematis buchaniana*. Both the leaves and flowers of this plant are ornamental and the flowers are very

fragrant. The blooming period begins about September and lasts until freezing weather.

Daffodils, T. BARR (*Jour. Hort.*, 52 (1900), Nos. 2718, p. 396; 2719, p. 416).—A historical sketch.

Notes on the honeysuckles, E. A. POPEÑO (*Amer. Gard.*, 22 (1900), No. 318, p. 57).—The character and method of propagation and culture of a number of shrub and twining species of *Lonicera* are reported.

The raising of orchids from seed (*Gard. Chron.*, 3. ser., 28 (1900), No. 725, pp. 350, 351).—Details of a successful method of growing orchids from seed.

Methods for growing seed from *Phlox divaricata*, *Daphne cneorum*, *Toxicophloe thunbergi*, *Yucca filamentosa*, M. LOBNER (*Gartenflora*, 50 (1901), No. 2, pp. 44-48, figs. 5).—The successful methods of the author in fruiting these plants are outlined.

International Congress of Rose Growers (*Jour. Soc. Nat. Hort. France*, 4. ser. 1 (1900), Oct., pp. 693-740).—In addition to the official proceedings of the society, the text of the following papers, which were read at the meeting of the society in Paris, June 14, 1900, is given: Classification of roses, Virger; Are there races of roses? Viviani-Morel; Hybridity, Allard; The influence of scion on the stock; The different forms of roses and their characteristics, Meyran; Study of the better varieties of China roses adopted by the congress, Meyran.

DISEASES OF PLANTS.

Some field experiments with formalin, M. B. THOMAS (*Proc. Indiana Acad. Sci.* 1898, pp. 62-64).—An account is given of field experiments with oats for the prevention of smut by treating the seed with $\frac{1}{2}$ per cent solution of formalin, after which the seed was sown broadcast. Untreated oats were sown at the same time, and so far as early appearances were concerned no difference could be observed as a result of the treatment. The mature plants from the treated seeds were slightly smaller than those from the untreated ones, but the amount of grain produced was the same in both cases. Upon ripening, the plants of the untreated seed showed 6 per cent smutty heads, while there was not a trace of smut to be found on any of the plants grown from the treated seeds.

In experiments with corn in which the grain was soaked in a 1 per cent solution, the seeds were delayed somewhat in their germination, but the early attacks of smut were totally prevented by the treatment. Later infection during the growth of the plant was not prevented by the use of the fungicide.

Seed treatment for the prevention of beet diseases, M. HOFFMANN (*Deut. Landw. Presse*, 27 (1900), No. 66, pp. 819, 820).—An account is given of experiments in which the effect of seed treatment on the germination of seed and the prevention of some of the diseases of beets were investigated. Different lots of beet seed were soaked for 20 hours in a 1 per cent solution of carbolic acid, for 30 minutes in concentrated sulphuric acid, after which they were washed in fresh water and milk of lime; for 20 hours in a 2 per cent solution of lysol,

and for 2 hours in a 1 per cent solution of calcium chlorid. The results of the germination tests of the treated seed are shown, comparisons being made with seed soaked 6 hours in water. With the exception of the seed treated with lysol, the germination of the other lots of treated seed exceeded the check, while the number of diseased plants was less.

A second series of tests is reported, in which the effect of treatment on diseases is shown. Normal seed gave 23.3 per cent of diseased plants, and treated seed gave the following percentages of diseased plants: Soaked in concentrated sulphuric acid, as above, 12.5 per cent; seed removed from seed ball and treated with sulphuric acid, 14.3 per cent; soaked 24 hours in Bordeaux mixture, 20 per cent; shelled and soaked in Bordeaux mixture, 16.6 per cent; soaked for 24 hours in a copper sulphate-soda mixture, 12 per cent; shelled and soaked in a copper-soda mixture, 9.2 per cent; shelled seed untreated, 10.7 per cent diseased.

As a result of his investigations, the author recommends as the best and surest method of treatment the soaking of the seed in sulphuric acid, as described above. The efficiency of the treatments with calcium chlorid, copper-soda mixture, and carbolic acid is in the order named. The last named should not exceed a $\frac{1}{2}$ per cent solution. The experiments in shelling seed showed that the advantage derived from the treatment does not compensate the additional cost.

The rotting of greenhouse lettuce, G. E. STONE and R. E. SMITH (*Massachusetts Hatch Sta. Bul. 69, pp. 40, pls. 2, figs. 9, dgm. 7*).—The forcing of lettuce, which has become a very important industry in Massachusetts, is liable to great loss on account of a number of parasitic diseases to which the plants are subject. The authors have been carrying on the investigations for 5 years relative to a cause of these diseases and means for their prevention. Their experiments have at last been brought to such a point of completeness as to warrant publishing the results in detail. The technical portions of their investigations have been already published (*E. S. R.*, 12, p. 764).

As the result of their studies it was found that great confusion has existed as to the cause of a number of diseases of lettuce. The fungus most generally described as causing lettuce diseases is *Botrytis vulgaris*. This fungus is said to occur rather rarely as a parasite on well-grown lettuce. It is commonly associated with the diseases indefinitely known as "damping off," mildew, black root, and rot. The most serious disease of forced lettuce is that called "drop." This disease has been found to be caused by the fungus *Sclerotinia libertiana*, which has not previously been described as occurring on lettuce, but is known to cause similar diseases on a number of other plants. It is a fungus that spreads through the soil and does not yield to the ordinary methods of prevention. It is an active parasite, attacking and killing every

plant with which it comes in contact. The presence of a white mold at the base of the plant, rotting the leaf bases and the stem, and a sudden collapsing of plants, distinguish this disease from the Botrytis diseases with which it has been confused.

Another disease which is due to a species of *Rhizoctonia*, in which the lower leaves are first attacked, moist brown spots occurring, and the leaf blade rapidly rotted away, is briefly described. In this disease the center of the head becomes a black, slimy mass. A brief note is also given on a bacterial disease, which so far the authors have not met with in their investigations.

An extended account is given of experiments conducted for the control of the "drop" and *Rhizoctonia* diseases by sterilizing soil. Experiments show that where $\frac{5}{8}$ to $\frac{3}{4}$ of an inch of sterilized sand or earth is used as a covering to the buds the amount of disease is reduced 47 per cent; 1 in. of sterilized sand or earth reduces it 87 per cent; and when 2, 3, or 4 in. have been sterilized there is no disease whatever, when the plants had not been infected from contaminated material. The sterilization of soil is affected by heating it to about 160° F. Other methods of preventing these diseases were investigated, but aside from sterilization none were efficient. Freezing the soil had no effect upon the drop disease, and the development of the sclerotia was considerably accelerated by freezing. Drying the soil has a similar effect. The sterilization method of treatment will have no value upon such diseases as the Botrytis, mildew, bacterial rot, etc., which can be readily prevented by proper management of the crops, spraying, etc.

Orange culture and diseases, J. BORG (*Bul. Bot. Dept. Jamaica, n. ser.*, 7 (1900), No. 9, pp. 129-142).—This paper gives an account of orange culture and diseases in Malta. The principles of culture are briefly outlined and the diseases treated under the heads of insect diseases, those caused by fungus parasites, those due to errors in assimilation or unsuitable surroundings. Among the insects noted as most troublesome are 2 species of flies (*Halterophora capitata* and *H. hispanica*), and numerous scale insects. Of the fungus diseases described, the black blight or fumago, due to *Meliola penzigi*, the gummosis due to a number of species of *Fusarium*, *Cladosporium*, etc., and to the attacks of *Polyporus obliquus*, are described at some length. The diseases due to imperfect assimilation and improper surroundings are briefly described. Among these diseases are mentioned withers or lupa, which is the sudden death of part or the whole of a tree caused by the sudden occurrence of cool breezes after a protracted sultry calm in the hottest days of summer. It is said to be purely a physical disease, and frequent irrigation is suggested as the only remedy. Other diseases are brontosia, which is a name given to a disease causing the sudden death of trees in the winter; anthomania, the production of an extraordinary quantity of flowers; anthoptosis, the fall of

flowers without blooming; and carpoptosis, the fall of young fruit. These diseases seem to be due to defective nutrition and are largely influenced by the meteorological conditions of the season in which they appear.

A fig disease, G. MASSEE (*Gard. Chron., 3. ser., 28 (1900), No. 706, p. 5, fig. 1*).—A fig disease, due to *Cercospora bolleana*, is described. The fungus is of wide distribution, being known to occur throughout the entire Mediterranean region, in Austria, and also in Argentina. The leaf of the plant is the part most generally attacked, the fruiting branches of the fungus forming olive-green patches on the under surface of the leaf. On the upper surface, over these discolored areas, the leaf assumes a brown or russet tinge, eventually turning yellow and dropping. When a loss of foliage occurs on a large scale, the fruit is arrested in its development and also falls off at an early stage. In some instances the young fruits are attacked. Although a very destructive parasite when present in quantity, it appears that no serious attempt has been made to arrest its progress beyond collecting and burning its diseased fallen leaves. It is thought that spraying with Bordeaux mixture would doubtless be of service in preventing the spread of the fungus, if done in sufficient time.

The sulphuring of grapes, F. SIMONET (*Vigne Amer., 24 (1900), No. 5, pp. 143-145*).—The author reports upon a number of trials of a method of applying sulphur to the Othello variety of grapes. This variety is said to be extremely sensitive to the ordinary application of sulphur for the prevention of mildew. As a result of the experiments it is shown that these, or other very sensitive varieties, may be successfully treated for the prevention of oidium by applying the sulphur in what is termed the Garanger method, better known as "Grison liquid." This consists of boiling for 6 hours a mixture of equal parts of sulphur and recently slaked lime. The liquid is decanted off, and to each liter of the mixture from 40 to 60 liters of water are added. Four sprayings during the season are recommended.

Mercury in the products of vines sprayed with the mercurial mixtures, L. VIGNON and J. PERRAUD (*Sci. Amer. Sup., 49 (1900), No. 1262, p. 20238*).—On account of the rather wide use of corrosive sublimate as a fungicide, the authors have made an investigation of products of the grape to ascertain the percent of mercury in them. Draft wine, press wine, lees, the residuum, and the grapes themselves, from vines which had been treated with various fungicides containing corrosive sublimate, were investigated. The results of analyses show that the products of the fermentation of grapes treated with mercurial mixtures in the proportions tested contained only minute traces of mercury and consequently could be used without danger. The effect on the plant, however, showed that the use of corrosive sublimate was decidedly detrimental.

On the preventive treatment of smuts of cereals, G. ARIETE (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 405-449).—The literature of seed treatment for the prevention of smuts of cereals is briefly reviewed and an account given of experiments of the author in which copper sulphate, potassium sulphate, sodium sulphate, potassium permanganate, and formalin were used. The results of the different trials are given, from which it appears that all the fungicides exercised a beneficial effect in reducing the amount of smut, the best results being obtained when the seed was treated for 12 hours with a 5 per cent solution of copper sulphate, or 30 minutes with a 10 per cent solution, the results being practically identical. An extended bibliography of the subject concludes the paper.

Treatment of seed oats for smut, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 24, 25).—The cause and appearance of smut are described, and an experiment in which formalin was used as a preventive of oat smut is outlined. The oats were soaked for 2 hours in a solution of formalin, 1 lb. to 50 gal. of water. Comparisons were made with ordinary copper-sulphate treatment, the seed being sown upon contiguous areas. In its development from the grain treated with copper sulphate, smutty heads were numerous and conspicuous; while among the oats grown from the seed treated with formalin, but 2 or 3 smutty heads were found in a plat of about 2 acres.

Combating the corn smut (*Ustilago maydis*), S. DAVID (*Selsk. Khoz. i Lyesyov.*, 197 (1900), June, pp. 553-566).—By a series of experiments the author found that weak solutions of formaldehyde do not affect the power of germination of corn, but the spores of the corn smut are killed by such solutions. As the most suitable strength of the solution of formaldehyde, the author recommends one of 0.1 per cent, to whose action the seeds should be subjected for 4 to 5 hours.—P. FIREMAN.

Potato scab, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 22, 23).—A brief description is given of potato scab, together with results of a number of experiments for its prevention. The comparative value of gypsum, sulphur, corrosive sublimate, and formalin as means for the prevention of potato scab was tested. The results showed that formalin was not only the most efficient, but, being nonpoisonous, is easily handled.

Red mold of hops, W. H. HAMMOND (*Jour. Southeast. Agr. Col. Wye*, 1900, No. 9, pp. 19, 20).—The cause of this disease, which seriously affects the quality and yield of hops, is said to be the mildew of the leaves, *Sphaerotheca castagnei*. Applications of sulphur or solution of potassium sulphid are recommended.

Orobanche cumana, V. SOKOCHEV (*Selsk. Khoz. i Lyesyov.*, 196 (1900), Jan., pp. 15-26).—This parasite causes great injury to the sunflower in southern Russia. The author describes the germination and development of the plant parasite and the measures of combating it. The chief remedy is the pulling out of the parasite as soon as it shows itself and begins to blossom. This parasite suffers from the attacks of the fungus *Urocystis orobanches* and of the fly *Phytomyza orobanchia*.—P. FIREMAN.

Root knot of the peach, W. A. BOUCHER (*New Zealand Dept. Agr. Rpt.* 1900, p. 334).—An account is given of the occurrence of a disease of peach trees that is doubtless the same as crown gall. It is thought to have been introduced from California with a lot of peach seeds.

Bacteriosis of walnut, W. A. BOUCHER (*New Zealand Dept. Agr. Rpt.* 1900, pp. 334, 335).—A description is given of a bacterial disease of cultivated walnut trees. It is apparently the same as that occurring in California, which has previously been noted (*E. S. R.*, 11, p. 261).

A new injury to trees, AUFFENBERG (*Oesterr. Forst u. Jagdw. Ztg.*, 18 (1900), No. 50, p. 396).—Injury to vegetation about works erected for the manufacture of calcium carbide used in acetylene making is noted.

New disease on *Caragana arborescens*, A. YACHEVSKI (*Selsk. Khoz. i Lyesyov.*, 196 (1900), Mar., pp. 663-666).—The fungus discovered on the *Caragana* is taken by

the author to be a new species of the genus *Phleospora*, and he proposes the name *Phleospora caraganae* for it. The new species most resembles, in its external appearance, *P. argyrantha*. To protect the Caragana from the fungus, the author recommends the careful removal of the fallen leaves and the spraying of the trees in the spring with Bordeaux mixture.—P. FIREMAN.

Basal rot in narcissus, W. CRAWFORD (*Jour. Hort.*, 52 (1900), No. 2691, pp. 347, 348).—A description is given of what is said to be one of the most destructive root diseases of narcissus. The name basal rot has been applied to this disease and in the author's opinion it is due to a species of *Penicillium*. The first indication of the disease is in the brown markings on the bulbs. These may be very slight or change the whole outer appearance into a discolored mass. While the fungus is ordinarily considered a saprophyte, the author believes it to be the true cause of the disease and recommends for its prevention the frequent rotation of crops and the use of commercial fertilizers.

ENTOMOLOGY.

Proceedings of the twelfth annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Division of Entomology Bul. 26, n. ser., pp. 102, pls. 2, fig. 1*).—At this meeting, held in New York City June 22, 23, 1900, the following papers were read:

Objects of the Association of Economic Entomologists, C. P. Gillette (pp. 5-15).—This paper is the address of the vice-president and contains a discussion of the objects of the Association.

The establishment of a new beneficial insect in California, L. O. Howard (pp. 16, 17).—*Scutellista cynea* was brought to this country from Cape Colony by C. P. Lounsbury upon twigs infested with *Lecanium oleæ*. Previous attempts had been made in colonizing this parasite (E. S. R., 10, p. 1058).

Beneficial work of Hyperaspis signata, L. O. Howard (pp. 17, 18).—Brief notes on the agency of this insect in reducing the numbers of *Pulvinaria acericola* (E. S. R., 12, p. 160).

Some effects of early spring applications of insecticides on fruit trees, E. P. Felt (pp. 22-25).—Experiments were conducted in fighting the San José scale with mixtures of kerosene and crude petroleum in water in 20 and 25 per cent solutions, potash, whale-oil soap, and hydrocyanic-acid gas. The spraying was done on April 11 and the fumigation on April 19-21 on a mixed orchard of 100 young pear, peach, and plum trees. The results indicated that crude petroleum seriously injured the trees under certain conditions. The mechanical dilutions of this substance up to the strength of 25 per cent appear to be harmless if applied before the buds open.

The relations of Pimpla conquisitor to Clisiocampa americana, C. M. Wood and W. M. Fiske (pp. 33, 34).—This parasite is reported as attacked when nearly full grown by a secondary parasite, *Theronia fulrescens*. *Pimpla conquisitor* occurs both as a primary and as a secondary parasite of the tent caterpillar.

Observations on Diabrotica 12-punctata, A. L. Quaintance (pp. 35-40).—This beetle was reported as abundant in Georgia. The first

adults were seen March 12, the first signs of injury on May 2, and the first pupæ May 8. The insect was observed on a large number of food plants. Laboratory observations were made on the egg-laying habit and the extent of the life cycle. Experiments were conducted in planting corn deep, shallow, early, late, with an excess of seed in the hills, and drilled; plats were also planted with seed corn soaked in strong kerosene emulsion, diluted kerosene emulsion, chlorid of lime, or soaked in tar and in sulphur made adhesive by moistening with molasses; 1 plat was treated with kainit at the rate of 2,000 lbs. per acre; another plat was sprayed with kerosene emulsion around the hills; tobacco dust was also placed in each hill of 1 plat. The seed corn soaked in strong kerosene emulsion was considerably injured and a larger percentage of larvæ was noted in the plats treated with kainit than in other plats. None of the methods of treatment except late planting had any appreciable effect in reducing the number of larvæ.

Notes on some African ticks, C. P. Lounsbury (pp. 41-49).—A brief discussion of *Amblyomma hebraeum*, *Hyalomma aegyptius*, *Rhipicepalus decoloratus*, *R. evertsi*, *Onithodoros savignii*, and *Argas persicus*.

Notes on Coccidæ of Georgia, W. M. Scott (pp. 49-54).—Brief notes on about 40 species of Coccidæ observed in this State.

Notes upon the destructive green-pea louse for 1900, W. G. Johnson (pp. 55-58).—The brush and cultivator method is reported as being a simple and rather effective means of destroying *Nectarophora destructor*. No practical spraying method has been found.

Hydrocyanic-acid gas as an insecticide on low growing plants, E. D. Sanderson and C. L. Penny (pp. 60-66).—This paper contains a record of experiments in fumigating small plants in the field and in boxes. (See E. S. R., 12, p. 162.)

Notes from Delaware, E. D. Sanderson (pp. 66-72).—Brief notes on a number of injurious insects, including the horse bot fly, green-apple aphid, destructive green-pea louse, and ladybird beetles.

Aphelinus fuscipennis, an important parasite upon the San José scale in Eastern United States, W. G. Johnson (pp. 73-75).—Brief notes on the extent of parasitism of the San José scale by this parasite.

Entomological notes from Colorado, C. P. Gillette (pp. 76-80).—In experiments to test the extent of spring migration of the codling moth, a number of larvæ were found under bands around trees, but not sufficient to warrant the adoption of this method for combating the first brood. Brief notes are also given on the peach-twist borer, woolly aphid, San José scale, California mite, and *Laphygma flavimaculata*.

Notes on insects of economic importance for 1900, W. G. Johnson (pp. 80-84).—Brief notes on asparagus beetles, destructive green-pea louse, Mediterranean flour moth, and San José scale.

Insects of the year in Ohio, F. M. Webster (pp. 84-90).—Brief notes on the Hessian fly, fall army worm, *Carneades tessellata*, *C. insignata*,

onion thrips, destructive pea louse. *Myochrous denticollis*, *Harpalus caliginosus*, and *Saperda vestita*.

Notes from California, C. W. Woodworth (pp. 90-94).—Notes on *Lecanium oleæ*, the San José scale, codling moth, peach-twigg borer, phylloxera, and *Typhlocyba comes*.

Notes from Canada, J. Fletcher (pp. 94-96).—A brief account of *Cacæcia rosaceana* and some of the common insect enemies of roots, vegetables, cereals, forage plants, trees, and shrubs.

First report on insect pests for 1899, F. V. THEOBALD (*Jour. Southeast Agr. Col. Wye, 1900, No. 9, pp. 21-48, figs. 25*).—The author discusses the habits, life history, and remedial measures against the asparagus beetles (*Crioceris asparagi* and *C. 12-punctata*). Among the natural enemies of the first species the author mentions ladybirds, lace-wing flies, and *Anthocoris nemorum*. Hand picking of the larvæ is recommended in gardens which are badly infested with these insects. Chickens and ducks also render valuable service in reducing the number of the beetles.

A species of thrips is reported as injurious to the scarlet runner bean. Infested plants are readily discernible by the fact that the lower petals become rapidly shriveled from the attacks of this insect. A detailed description is given of the species, and brief notes on its life history. For combating this species, and also *Thrips pisivora*, the author recommends the destruction of all bark and rubbish under which the insects might hide and the use of such insecticides as pyrethrum and tobacco.

The author worked out anew the complete life history of the hop aphid (*Phorodon humuli*). The eggs of this species are found in winter on prune trees, and from these eggs viviparous wingless females are hatched, of which there were 3 generations. During June winged viviparous females were produced, some of which migrated to hops. In the fall female and male migrants returned to the prune trees, where the insect hibernated in the egg stage. The author believes that the cultivation of prunes and plums in the neighborhood of hop gardens is partly responsible for unusual outbreaks of the hop louse. Brief notes are also given on *Malolontha vulgaris* as an enemy of the hop. The burdock moth (*Gortyna flarago*) is reported as having caused considerable damage to tomatoes. The larvæ of this insect enters the stems of various other plants beside the tomato and burrows upward in the central pith. The recorded food plants of the species are ragwort, burdock, dock, and thistles. The author presents brief notes on the considerable number of injurious insects, among which mention may be made of flea-beetles on cabbage and other garden vegetables, apple-blossom weevils, wheat midge, and pear midge.

The Hessian fly in 1899 and 1900, F. M. WEBSTER (*Ohio Sta. Bul. 119, pp. 237-247*).—The Hessian fly was unusually destructive to

wheat in Ohio during the fall of 1899 and the spring of 1900. The conditions which were favorable to the relative abundance of the Hessian fly were the decrease in the number of its natural enemies, a mild autumn, and a severe drought which retarded the development of the fall brood to such an extent that the flies emerged in time to be most destructive to late sown wheat. The Hessian fly emerges about one month earlier in the fall over the northern parts of the State than in the southern parts. Throughout Ohio, except in the northwest and southwest portions, the rainfall in August, 1899, was below the normal. During September the temperature was low and heavy rains occurred on the 18th and 25th of this month. Soon after these rains the fall brood of the Hessian fly emerged and attacked the young wheat which required a longer time than usual for germination on account of the drought. The author believes that the Hessian fly will probably continue to be very destructive for another season. It is possible, however, for the farmer to regulate to some extent the time of sowing wheat by the weather conditions, remembering that the fall brood of the Hessian fly emerges within a few days after a heavy rainfall. It is not advisable to sow wheat for 2 successive years on the same ground and it should be remembered that the Hessian fly attacks rye and barley as well as wheat.

The Hessian fly in West Virginia and how to prevent losses from its ravages, A. D. HOPKINS (*West Virginia Sta. Bul.* 67, pp. 239-254, pls. 2, map 1).—The author gives a brief summary of the life history of the Hessian fly. In West Virginia there are 2 broods of this insect a year, and the time of appearance of the fall brood is modified more by altitude than by latitude. The author gives a brief statement of the ordinary methods used in controlling the Hessian fly, including burning of the stubble, plowing under stubble, destruction of volunteer wheat, sowing trap strips of wheat, and crop rotation. It is stated that the period for sowing wheat extends over about 15 or 20 days, beginning about a week earlier than the average date for the disappearance of the fall brood of Hessian flies, and ending from 1 week to 16 days later than this date. The disappearance of the fall swarm or period of active flight is, according to the author, governed by a natural law which "causes it to vary at the rate of about 4 days for each degree of latitude (earlier toward the north and later toward the south) and 4 days earlier for each 400 feet of altitude above sea level." The average dates for the disappearance of the fall brood in different parts of the State are given on a map which accompanies the bulletin.

Experiments with insecticides upon potatoes, C. D. WOODS (*Maine Sta. Bul.* 68, pp. 169-192).—This bulletin contains a report upon experiments with several commercial insecticides in comparison with Paris green as a remedy for the potato beetle. For these experi-

ments a ten-acre field was placed at the disposal of the experiment station. This field was planted with Green Mountain potatoes in April and divided into 14 plats of 16 rows each, with 2 plats of shorter rows at either end. As insecticides Paris green, Boxal, Paragrene, arsenate of lead, and Arsenoids Nos. 2, 3, 4, and 5, were used. The insecticides were applied with water, together with a fungicide, either Bordeaux mixture or other similar materials. One-half the field was sprayed July 11 and the other half on July 13. The whole field was sprayed July 21 and 27 and one-half on August 10 and the other half on August 11. A Vermorel nozzle was used for the first application over each row and the rows were passed over twice in opposite directions. The other applications were made with a double Vermorel nozzle.

Three applications of Paris green at the rate of $\frac{1}{2}$ lb. per acre kept the potato beetles so reduced in numbers that the fourth application on August 10-11 was unnecessary. Applied at the rate of $\frac{1}{2}$ lb. to 2 lbs. of lime per acre, Paris green was more effective in killing the bugs than when mixed with Bordeaux mixture, the latter being apparently so distasteful to the beetles that they left the thoroughly sprayed leaves, and thus avoided the leaves with the most Paris green. Paragrene was applied 4 times with Bordeaux mixture at the rate of $\frac{1}{2}$ lb. per acre. The Paragrene used in the experiment was coarser than Paris green, and there was some residue which would not go through a fine Vermorel nozzle. The potato beetles were all destroyed, and only a slight injury to the foliage was noticed. Field notes made on the experiments with the Arsenoids show that these substances were as effective as Paris green, but less so than arsenate of lead. They contain more free arsenious acid than the best Paris green. Arsenate of lead is the poisonous element in Boxal and Disparene. Rows 97 to 112 were treated 4 times with arsenate of lead and Bordeaux mixture at the rate of 1 lb. per acre. On August 14 it was noted that the beetles were all destroyed. Boxal was also applied 4 times at the rate of 5 lbs., and in another plat at the rate of 10 lbs. per acre. The larger application was more effective in destroying the potato beetles. Disparene was applied to a field of 3 or 4 acres with satisfactory results.

A number of experiments were conducted with Bug Death as an insecticide. It was found that this substance would cost \$8 per acre for each application and that 2 applications about a fortnight apart would be necessary to free the potatoes from the beetles. The process of applying this insecticide is slow and laborious. The substance is chiefly zinc oxid and contains no nitrogen and only a trace of phosphoric acid and potash. It can not therefore be considered a fertilizer. At the rate of 100 lbs. per acre this substance freed potato vines from the beetles. The beetles, however, were not killed but merely driven

away. The great cost and slow process of application of this substance renders it an imperfect insecticide. Black Death was also applied once on $\frac{1}{4}$ acre of potatoes at the rate of 40 lbs. per acre. It had no appreciable effect upon the beetles.

The author concludes that there is no good substitute for arsenical poisons in combating the Colorado potato beetle. Arsenical poisons are best applied with water in the form of a fine spray in conjunction with Bordeaux mixture or lime. Some of the cheaper arsenoids were as effective as Paris green. Lead arsenate was the most satisfactory of all insecticides used during the experiments.

Economic and biological notes on insects injurious to herbageous crops in the Valley of Bientina, G. DEL GUERCIO (*Nuove Relaz. R. Staz. Ent. Agr.*, 1. ser., 1900, No. 2, pp. 269-303, figs. 31).—A critical review is presented of the literature relating to *Agrotis ypsilon*, in connection with a brief bibliography of the subject. Detailed descriptions are given of this insect in all its stages, and a brief discussion is presented of its life habits and metamorphoses. The more common host plants of this insect in Italy are said to be beans, kidney beans, potatoes, hemp, tobacco, cotton, etc. The conditions which are favorable to the development of this insect are a dry, windy winter, followed by a spring relatively cold and wet. The insects which were noticed preying upon this cutworm were *Hister 6-striatus*, *Formica rufa*, and *Polyergus rufescens*. A bacterial disease was noticed among the cutworms and several cutworms were destroyed by *Oospora guerciana*. The more important insect parasites are *Meteorus scutellator*, *Microplitis mediana*, *Erigorgus melanobatus*, *Ceolopistus cephalotus*, etc.

The author recommends the usual remedies adopted for cutworms and army worms in combating this insect.

The effect of scale lice upon vegetable tissues, J. KOCHS (*Bot. Mus.*, Abt. Pflanzenschutz, Hamburg, 2 (1900), pp. 16).—The author made an investigation of the cause of spots of various colors found on the exterior of fruits. Red spots were found on peaches, pears, and apples, and were due to the attack of *Diaspis pentagona*, the San José scale, Forbes scale, Putnam scale, and the scurfy scale. Yellow spots were found on pears and were due to the attack of the oyster-shell bark-louse and *Aspidiotus pyri*. Yellowish green spots were found on apples, and were caused by the presence of *Rastelia pirata*. Green spots observed on apples and lemons were attributed to the attacks of *Aspidiotus ancyclus* and *A. nerii*. Bleached spots were observed on oranges, and were caused by the attack of *Purpatoria proteus* and *P. zizyphi*.

On the skins of oranges only a slight discoloration was produced by the attacks of scale lice, while ripe lemons showed round spots of 10 mm. from the same cause. An investigation of the green spots showed

an absence of soluble yellow coloring matter, while chlorophyll grains were present in abundance. A similar local checking of the ripening process was also observed on varieties of apples attacked by various fungi. In investigating the red spots, 2 forms were distinguished. The one is in the cavities in either end of the fruit, while the other was found on the convex surface of the fruit. In the former case, the spots were elongated and arranged somewhat in a radial manner about the center of the cavity, while in the second case, the spots were more nearly round. The San José scale was found to produce the largest and most intensely colored spots. In these respects the Putnam scale comes second in the series, and the Forbes scale third. The form of the spots produced by the scurfy scale is peculiar, appearing nearly as a double spot in each case. The author believes that the formation of red spots is due to a hastening of the maturation process, which takes place at the point where the beak of the insect is inserted. The stable carbohydrates are believed to be changed by means of enzymes which come from the infecting insects.

The author further discusses the various forms of local swellings and excrescences produced on fruits and other vegetable tissues by the attacks of various scale lice.

Economic and biological notes on *Simæthis nemorana* (*Nuove Relaz. R. Staz. Ent. Agr.*, 1, ser., 1900, No. 2, pp. 305-328, figs. 14, pl. 1).—This insect is distributed most abundantly, according to the author, through central Europe, while France and Italy seem to suffer most from its attacks. The host plant is the fig. The author describes the insect in all its stages. The insect attacks the buds, leaves, and bark of the tender twigs of the fig. The conditions most favorable for the development and wide distribution of this insect are an abundance of the fig and sunny localities well protected from the wind. The insect parasites which assist most materially in checking the ravages of this fig insect are *Angitia armillata*, *Pimpla alternans*, *Phaenogenes impiger*, and *Musocera casta*.

A number of insecticides were used in combating this insect, among which the following may be mentioned: Soap 2 kg., water 100 liters; soap 1½ kg., carbon bisulphid 0.3 liter, water 100 liters; alkaline tar 2 kg., water 100 liters; alkaline tar 1½ kg., bisulphid of carbon 0.3 liter, water 100 liters.

Observations on the development and use of the locust fungus in German southwest Africa, RICKMANN AND KAESWURM (*Notizbl. K. Bot. Gartens u. Mus., Berlin*, 3 (1900) No. 24, pp. 65-74).—The authors received 50 test tubes containing cultures of the locust fungus from Cape Colony. Experiments were made in transferring this material to other test tubes for the purpose of obtaining pure cultures. Microscopic examinations of the material showed that the fungus was closely related to *Mucor racemosus*. Experiments with this fungus indicated

that the locusts died from 4 to 6 days after being inoculated. The best results were obtained in the presence of a moderately moist surrounding. In spreading the infection several methods may be adopted. A number of locusts may be captured, dipped in a solution containing the fungus, and then replaced in the swarm. Small areas of ground frequently visited by the locust may be infected with the same solution. For infecting the locust in the immature wingless stages, about a pound of white bread was dried, pulverized and made into a rather thick gruel; this mass was then inoculated with pure cultures of the fungus, and after the fungus had developed so as to be readily seen, portions of the infected mass were placed in locations where the immature locusts might be likely to feed.

The honeybee, G. G. NAYLOR (*West Virginia State Bd. Agr. Rpt. 1899-1900*, pp. 202-209).—Popular notes on *Apis dorsata* and on various practical matters connected with bee keeping.

Apiarian notes, J. P. PROVAN and H. G. BURNET (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 1, pp. 663-666).—The authors found that the amount of swarming was considerably reduced where 20 frames were allowed for each queen. The Italian bees did not swarm as much as the dark hybrids, and the queens of the latter were therefore killed off and replaced with Italian queens.

The determination of sex in bees, SCHILLER-TIETZ (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 18, pp. 665-673; 19, pp. 715-717; 20, pp. 755-760).—In this article the author presents an elaborate discussion of the problem of the determination of sex in the honeybee. The author does not accept in its entirety either the theory of Dzierzon or that of Dickel, but inclines to the belief that the sex of the bees is already determined in the egg at the time it is laid.

The pantry moth, S. F. AARON (*Sci. Amer.*, 83 (1900), No. 16, pp. 250-253, figs. 7).—Brief notes on the life history, habits and means of combating *Plodia interpunctella*.

Bibliography of clinical entomology, J. C. HUBER (*Bibliographie der klinischen Entomologie*. Jena: H. Pohle, 1899, Nos. 1, pp. 24; 2, pp. 24; 3, pp. 25; 1900, No. 4, pp. 27).—The author gives bibliographical references on literature relating to *Sarcophylla*, *Pulex*, *Acanthia*, *Pediculidæ*, *Demodex*, *Leptus*, *Dermanyssus*, *Argas*, *Ixodes*, *Pediculoides*, *Tetranychus*, *Tyroglyphus*, *Sarcophila*, *Sarcophaga*, *Calliphora*, *Anthomyia*, *Musca*, *Lucilia*, *Teichomyza*, *Compsomyia*, *Hypoderma*, *Dermatobia*, *Ochromyia*, *Sarcoptes scabiei*, and *Symbiotes felis*.

A list of the biting lice (Mallophaga) taken from birds and mammals of North America, V. L. KELLOGG (*Proc. U. S. Nat. Mus.*, 22 (1900), pp. 39-100).—The author presents an analytical table for the determination of species belonging to this order of insects. The species are listed with bibliographical notes and indications of their hosts. The number of Mallophaga recorded from North American host animals amounts to 282 species, of which 264 are from birds and 18 from mammals. A list is also given of the host animals, with indications of the Mallophaga which occur upon each species.

Report of the botanist and entomologist, G. W. HERRICK (*Mississippi Sta. Rpt. 1900* pp. 40-42).—The liming of soil apparently had a beneficial effect in checking the development of tomato blight. The author has undertaken work on insects injurious to pecans. Experiments were conducted for the destruction of horn-fly. Cattle were sprayed with mechanical mixtures of kerosene and water containing 10, 15 and 17 per cent. It was found that the flies were destroyed if the spray was brought in contact with them. They frequently leave the back of the animal and lie upon the belly, and it is therefore necessary to direct the spray accordingly.

Insects injurious to garden and field crops, fruits, forest trees, man, and domestic animals; their life history, injuries and methods of preventing them. III. Hymenoptera and Diptera, G. LEONARDI (*Sci. Prat. Agr.*, 11 (1900), No. 3, pp. 549, figs. 249).—This book constitutes Vol. 3 of a general treatise on injurious insects, of which Vol. 1 was published in 1889, and covered the subject of general entomology and Coleoptera; and Vol. 2 was published in 1894, and included a discussion of injurious Lepidoptera. These 2 volumes were written by A. Lunardonì. The present volume gives a discussion of the life history and habits of injurious Hymenoptera and Diptera, together with suggestions of the approved remedies for combating these insects. A very large number of species is included, the discussion of which species is fairly complete. The family Pulicidæ is included under the Diptera. Extensive bibliographical references are given in the volume.

The plagues of field crops, P. CONDE (*Bol. Soc. Nac. Agr. [Lima]*, 4. ser., 11 (1900), No. 3, pp. 170-172).—Brief general notes on the depredations committed by injurious insects upon the common field crops.

Losses caused by the grain aphid, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 25, 26).—Several heads of each of a large number of varieties of wheat were inclosed with a netting so as to prevent the attacks of the grain aphid. One hundred grains from such heads were then compared in size, weight, and appearance with 100 grains of the same variety from heads which had been infected with the grain aphid. It was found that before the grain had been allowed to dry, the weight of the protected and unprotected grain of any variety was approximately the same. During the process of drying, however, the grains from infected heads shriveled up to a considerable extent and the loss in weight as compared with grain from uninfected heads was found to be from 15 to 35 per cent.

The economic entomology of the sugar beet, S. A. FORBES and C. A. HART (*Illinois Sta. Bul.* 60, pp. 397-532, pls. 9, figs. 97).—In this bulletin the authors have compiled brief accounts of the habits, life histories, and means of combating all insects which are known to attack the sugar beet in the United States. The number of species discussed is about 150. A bibliography of the subject is added to the bulletin.

The locust plague and its suppression, A. MCNRO (*London: John Murray*, 1900, pp. 365, figs. 45).—The author gives a detailed discussion of the locust plague in Argentina and in South Africa. The subjects considered in the volume include an account of the appearance, habits, and life history of the locust, correspondents' and newspaper accounts relating to the subject, and an elaborate discussion of the natural enemies and artificial means for combating these insects. The natural agencies recognized by the author are winds, birds, reptiles, mammals, insect parasites, and fungus diseases. Among the mechanical means for fighting locusts mention may be made of trampling by means of herds of sheep and cattle, rolling with heavy rollers propelled by steam or in front of horses; the use of wire flails; and various forms of hopperdozers and Carcaranya machines. A considerable discussion is also given to various forms of traps, ditches and trenches with and without water, pits, barriers of various sorts, burning, and scalding by means of steam. Among the chemical substances used in the destruction of locusts the following are discussed: Arsenical solutions, arsenic and treacle, Paris green, London purple, coal tar, creosote, paraffin, carbolic acid, and petroleum.

Locust destruction (*Agr. Jour. Cape of Good Hope*, 17 (1900), No. 11, pp. 684-686).—The Government of the Cape of Good Hope has undertaken to bear two-thirds of the expense of spraying materials and to furnish spray pumps where possible, for the purpose of destroying swarms of immature locusts. The sprays which were recommended are Blue Mottled Soap, Little's fluid dip, Odam's fluid dip, glycerin dip, and Sunlight Soap. W. R. Ellis reports the results from using some of these dips. Odam's dip used in the proportion of 1 gal. to 5 gal. of cold

water killed all locusts in from 5 to 15 minutes. Blue Mottled Soap in proportion of 1½ lbs. to 5 gal. of water caused the death of locusts upon which it was sprayed within about 5 minutes.

Injurious fruit insects; insecticides; insecticide apparatus, R. A. COOLEY (*Montana Sta. Bul. 23, pp. 64-114, figs. 39*).—Brief popular notes on the codling moth, tent caterpillar, gooseberry fruit worm, pear slug, round-headed apple-tree borer, flat-headed apple-tree borer, plum curculio, San José scale, oyster-shell bark-louse, scurfy bark louse, woolly aphid, tarnished plant bug, pear psylla, currant flies, and pear-leaf blister mite. Directions are given for the preparation and use of the common insecticides.

Ceratovacuna lanigera, the white plant louse of the sugar cane leaves, L. ZEHNTNER (*Meded. Proefstat. Suikerriet, West Java, No. 49, pp. 30, pls. 2*).—The author believes that the injury caused to sugar cane by this species is greater than has usually been supposed. The insect is described in detail in all its stages. The natural enemies of these plant lice are rather numerous and active in its destruction. Among the more important ones mention may be made of *Encarsia flavoscutellum*, species of *Chrysopa*, *Osmylus*, ladybirds, and *Ephestia cautella*.

Scale lice. Description and means of combating the most important scale lice of the German fruit and grape industries, A. B. FRANK and F. KRÜGER (*Schildlausbuch. Beschreibung und Bekämpfung der für den deutschen Obst- und Weinbau wichtigsten Schildläuse. Berlin: Paul Parey, 1900, pp. 120, figs. 59, pls. 2*).—This work contains a general discussion of the biology and economic importance, and means of combating the more injurious scale lice of Germany. The following subjects are considered: Classification of the subfamilies of scale lice; the development of scale lice; methods of reproduction; their influence on the host plants; means of infestation of fruit trees and the natural enemies of scale lice; the direct and indirect artificial remedies, including the care of trees, mechanical and chemical remedies, such as lime water, arsenical preparations, creosol, lysol, soaps, petroleum, and hydrocyanic-acid gas; a descriptive and systematic account of the genera *Aspidiotus*, *Diaspis*, *Mytilaspis*, *Parlatoria*, *Lecanium*, and *Pulvinaria*; and tables for the identification of the more important species.

Scale on fruit trees (*Jour. Jamaica Agr. Soc., 4 (1900), No. 12, pp. 719, 720*).—This paper constitutes the first of a series of leaflets which are to be issued by the Board of Agriculture. It contains directions for preparing kerosene emulsion.

Locomotion of the larvæ of scale lice, L. REH (*Bot. Mus., Abt. Pflanzenschutz, Hamburg, 2 (1899-1900), pp. 6*).—In order to determine the rapidity with which the larvæ of scale lice may move, the author placed a number upon a sheet of paper and traced the course of the larvæ by means of a pencil. It was found that the larvæ of the oyster-shell bark-louse moved from 1½ to 2 cm. per minute, while the larvæ of *Diaspis ostreaformis* traveled about 1½ cm. per minute.

How to control the San José scale, C. L. MARLATT (*U. S. Dept. Agr., Division of Entomology Circ. 42, 2. ser., pp. 6*).—The author believes that the San José scale can not be exterminated where it has once become well established, but that it can be successfully controlled. The most important insecticide methods for controlling this insect are the lime, salt, and sulphur wash in California and in the East whale-oil soap, pure kerosene, crude petroleum, mechanical mixtures of either kerosene or crude petroleum with water, and fumigation with hydrocyanic-acid gas. Brief directions are given for the preparation and use of these insecticides.

The structure of the border of the last abdominal segment of the San José scale, H. MEERWARTH (*Bot. Mus., Abt. Pflanzenschutz, Hamburg, 2 (1899-1900), pp. 15, pl. 1, figs. 5*).—This article is a detailed study of various anatomical features connected with the exterior of the posterior abdominal segment of this insect.

Report on the activity of the section for plant protection for 1899, C. BRICK (*Bot. Mus., Abt. Pflanzenschutz, Hamburg, 2 (1899-1900), pp. 3*).—The author

gives a detailed report on the number of crates, barrels, and baskets of fresh American fruit received in Hamburg, and on the proportion which were found to be infested with the San José scale.

Aspidiotus ostreæformis and related species, L. REH (*Bot. Mus., Abt. Pflanzenschutz, Hamburg*, 2 (1889-1900), pp. 13, fig. 1).—Upon examination, the author found that the species hitherto known in Germany as *A. ostreæformis* is really *A. pyri*, and that the true *ostreæformis* also occurs in Germany. The detailed description of the species is therefore given.

Sumach as a remedy for combating Phylloxera, G. FLORIANO (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 1, pp. 45-55).—Infusions of the wood and leaves of this plant were placed in the soil around infested grapevines for the purpose of determining whether the substance had any destructive effect upon Phylloxera. Entirely negative results were obtained in all experiments.

The life history of Arctia phalerata, A. GIBSON (*Canad. Ent.*, 32 (1900), No. 12, pp. 369-376).—The author describes the egg of this species, 7 stages in the larval development, and the pupa. The length of the pupal stage was found to be about 12 days. The food plants of the first brood were dandelion and plantain; the second brood was found only on the dandelion.

The structure and life history of the harlequin fly, L. C. MIALL and A. R. HAMMOND (*Oxford: Clarendon Press*, 1900, pp. 191, pl. 1, figs. 129).—In this book the authors have described in detail the life history and relations of *Chironomus dorsalis* to other Diptera, the larva, pupa, adult and embryonic conditions, and various anatomical, histological and other details connected with the structure of this insect. A bibliography is appended to the book.

On the genera of the chalcid flies belonging to the subfamily Encyrtinae, W. H. ASHMEAD (*Proc. U. S. Nat. Mus.*, 22 (1900), pp. 323-412).—The author gives an analytical table for the determination of species, together with descriptions of a number of new species.

A new sporozoon in the larvæ of Diptera, L. LÉGER (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 18, pp. 722-724).—A new species of this group of animal organisms was found in larvæ of the genus *Ceratopogon*, and is named *Schizocystis gregarinoides* by the author. Brief notes are given on the anatomical characters and metamorphoses of this parasite in the intestines of the host.

Note on Cordyceps sinclairii, W. B. BENHAM (*Trans. and Proc. New Zealand Inst.*, 32 (1899), pp. 4-8, pl. 1).—This species of fungus was found by the author in New Zealand, infesting the larva of a species of Cicada. The fructification of most of the species of *Cordyceps* hitherto studied is known only in the ascospore stage. This species, on the other hand, was found by the author in the conidiospore stage.

Directions for collecting and rearing dragon flies, stone flies, and May flies, J. G. NEEDHAM (*Ext. U. S. Nat. Mus. Bul.* 39, 1899, pp. 9, figs. 4).—Brief directions for collectors and students of these groups of insects.

Fumigation with hydrocyanic acid, H. H. COUSINS (*Jour. Southeast Agr. Col. Wye*, 1900, No. 9, pp. 67-70).—Experiments were made in cooperation with Mr. T. V. Theobald, in treating currant bushes by this method for black currant bud mite. Infested currant bushes which were intended for planting were placed in a heap on the ground, covered with canvas and subjected to the fumes of hydrocyanic acid for about one hour. All the mites were killed by this treatment. In applying this method to currant bushes growing in the field, it was found that the chemicals would cost about \$12 per acre.

Experiments with hydrocyanic-acid gas were also made in vineries and green-houses, for the purpose of testing the efficiency of this method in destroying the mealy bug. The experiments gave satisfactory results and no injury was noted on the foliage of chrysanthemums, maidenhair ferns, and other plants which were subjected to the treatment.

FOODS—ANIMAL PRODUCTION.

Studies on the amount of nutrients required by man at rest, K. ELKHOLM (*Skand. Arch. Physiol.*, 11 (1900), Nos. 1-2, pp. 1-96, *diags.* 2).—The balance of income and outgo of nitrogen was studied with students, soldiers, and aged men, the Söndén and Tigerstedt respiration apparatus being used (E. S. R., 8, p. 242). The energy furnished by the food consumed and utilized by the subjects is calculated. The author discusses his results at length, comparing his experiments with similar investigations made elsewhere. According to the author, the students in these experiments required on an average 1,156 calories per square meter of surface area; the soldiers, 1,186 calories; or taking the average of the two groups of young men, 1,171 calories. A man weighing 70 kg., whose surface area equals 2.0912 square meters, would therefore need daily 2,450 calories net, while on the supposition that 10 per cent of the fuel value of the food is lost in the feces, he would need a total of 2,700 calories, or calculated on the basis of body weight, 35 and 38.6 calories, respectively, per kg. The author believes further that the results of the numerous dietary studies which have been made are in accord with these values. The article concludes with an extended bibliography.

On the elimination of nitrogen, sulphates, and phosphates after the ingestion of proteid food, H. C. SHERMAN and P. B. HAWK (*Amer. Jour. Physiol.*, 4 (1900), No. 1, pp. 25-49, *diags.* 3).—The authors (healthy young men under normal conditions of nutrition) were themselves the subjects of experiments in which the amount of protein was increased at different times in an otherwise practically uniform diet. In one case the fat was correspondingly diminished. The income and outgo of nitrogen were determined, as well as the heat of combustion of the urine. The excretion of nitrogen, sulphur, and phosphorus in the urine was determined at frequent intervals with the object of ascertaining how soon after the consumption of protein its cleavage products are excreted.

"As measured by 3-hour periods, the rates of excretion of nitrogen and sulphates run closely parallel and normally show a tendency to rise during the morning, reaching a maximum after the midday meal, with a slight fall in the following period and another rise after the evening meal. During the night the excretion usually reaches the minimum.

"The excretion of phosphates on the normal days described a curve altogether different from that of nitrogen and sulphates, rising steadily from the middle of the morning until the time of retiring, then falling during the hours of sleep and continuing to fall for 3 hours after rising, reaching a minimum after breakfast.

"When lean beef sufficient to furnish about 63.7 gm. of extra protein was taken with breakfast, the nitrogen began to rise in the first 3 hours and reached a maximum between the sixth and ninth hours, after which it declined at first rapidly and then more slowly, reaching the normal after about 36 to 39 hours.

"The increased excretion of sulphates was proportional to that of nitrogen and followed the same general course. It appeared, however, to begin a little later, and certainly regained the normal a little earlier.

"The increase in the rate of excretion of phosphates apparently began a little later, but reached a maximum at the same time with that of nitrogen, after which it fell rapidly, regaining the normal about 12 to 15 hours after the ingestion of the beef.

"The increased heat of combustion of the urine was but little greater than would correspond to an amount of urea equivalent to the extra nitrogen eliminated. This would seem to indicate that the total amount of the less highly oxidized constituents of the urine was but little affected.

"The nature and extent of the changes in the urine seem to have been about the same when the protein was simply added to the diet as when it was substituted for an isodynamic amount of fat.

"A moderate gain or loss of body nitrogen does not seem to affect the changes noted."

Digestion trials, J. FIELDS and A. G. FORD (*Oklahoma Sta. Bul. 46, pp. 8*).—The digestibility of a number of grains was tested with chickens and that of forage crops with sheep.

Digestion trials with chickens.—The digestibility of Kafir corn, maize, and cowpeas, ground and unground, was tested with 3 cockerels. The experiments in general consisted of a 5-day period preceded by a preliminary period of 2 days. The chickens were supplied with coarse sand and water, *ad libitum*. The amount of sand eaten was recorded and was quite considerable, ranging from 72.6 to 296 gm. per day. The average coefficients of digestibility obtained are shown in the following table:

Results of digestion experiments with chickens.

	Organic matter.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Kafir corn	87.7	52.9	20.1	96.3	73.7
Kafir corn meal	87.2	42.6	35.5	96.5	82.7
Maize	86.4	49.8	92.5	91.7
Maize meal	85.5	48.4	91.5	93.1
Cowpeas	71.5	40.5	18.4	87.1	88.7
Cowpea meal	72.2	43.7	9.6	87.8	88.7

"Chickens digested Kafir corn and corn more completely when the grain was fed whole than when the meal was fed. The Kafir corn and Kafir meal fed in this trial yielded but 2 per cent less total digestible matter than the corresponding corn products. Kafir corn was a more suitable ration, considering only the relative amounts of growth-making and fat-forming materials, for chickens than Kafir meal, corn, or corn meal. Cowpeas were digested reasonably well and are desirable feed for growing chickens and hens. But little gain in digestibility was secured by grinding the cowpeas."

Digestion trials with sheep.—The digestibility of a number of coarse fodders was tested with sheep. The average results follow.

Digestibility of a number of forage crops by sheep.

	Dry matter.	Protein.	Ether extract.	Nitrogen-free extract.	Crude fiber.	Ash.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Kafir	57.9	41.7	64.8	66.9	54.1	11.1
Corn	62.1	44.3	75.5	71.1	52.5	4.6
Small sorghum	56.0	15.7	75.2	67.0	46.3	12.4
Large sorghum	54.0	17.0	80.1	60.3	53.1	16.4
Black rice corn	52.0	25.3	64.2	62.1	44.5	20.6
Milo maize	51.7	16.2	63.0	60.7	50.9	7.7

Digestion experiments with sheep, J. M. BARTLETT (*Maine Sta. Bul. 67, pp. 133-168*).—Following the usual methods, experiments on the digestibility of a number of feeding stuffs were made with sheep, the average results of which follow:

Average digestion coefficients obtained with sheep.

Feeding stuff.	Dry matter.	Organic matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.	Ash.	Available fuel value.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Clover hay, cut in early bloom	57.6	59.0	65.9	27.9	62.9	51.8	44.6	53.3
Clover hay, cut in late bloom	55.6	57.2	67.3	35.4	64.3	43.6	38.5	51.0

Corn germ (fed with hay)	73.7	74.8	75.4	96.0	71.9	68.2	48.3	77.1

A comparison of determined and calculated heats of combustion, L. H. MERRILL (*Maine Sta. Bul. 67, pp. 169, 170*).—As illustrated by the values obtained with a number of samples of wheat and various milling products, the difference between the determined and calculated fuel value ranged from 0.026 to 0.430 calorie, or nearly 10 per cent of the total determined value. The variations according to the author are intimately connected with the amount of crude fiber present. “If this be true we should expect to find the greatest difference between the determined and calculated heats of combustion in those materials which are especially rich in fiber, such as the coarse fodders and feces of herbivorous animals.” The following results bear on this point:

Crude fiber and determined and calculated fuel value of a number of samples of feeding stuffs.

Feeding stuff.	Crude fiber.	Heat of combustion.		
		Determined.	Calculated.	Difference.
	<i>Per cent.</i>	<i>Calories.</i>	<i>Calories.</i>	<i>Calories.</i>
Oat hay	30.74	4.209	3.719	0.490
Sheep feces from oat hay	33.65	4.290	3.682	.608
Clover silage	33.43	4.184	3.638	.546
Sheep feces from clover silage	32.16	4.379	3.805	.574
Oat-and-pea silage	31.12	4.209	3.984	.225
Sheep feces from oat-and-pea silage	32.88	4.163	3.669	.494

In view of such variations as those noted above, a quantity of crude fiber was prepared from fodder and sheep feces and the heat of

combustion determined in the usual way. The results reduced to a water-free and ash-free basis follow:

Heat of combustion of crude fiber from fodders and feces corresponding to them.

Source of crude fiber.	Heat of combustion.	Source of crude fiber.	Heat of combustion.
	<i>Calories.</i>		<i>Calories.</i>
Oat hay.....	4.405	Feces from oat hay.....	4.662
Clover silage.....	4.610	Feces from clover silage.....	5.215
Oat-and-pea silage.....	4.667	Feces from oat-and-pea silage.....	4.820
Average	4.561	Average	4.899

"The crude fiber from the feces had, in these 3 cases, an average determined fuel value over 7 per cent higher than that of the fiber from the corresponding fodders. In other words, the digestible crude fiber had a lower fuel value than that remaining in the feces, and consequently, lower than that of the mixture of carbohydrates included in that term as found in the original fodders."

Experiments on the influence of asparagin and ammonia upon the metabolism of protein in herbivora, O. KELLNER ET AL. (*Ztschr. Biol.*, 39 (1900), No. 3, pp. 313-376).—The experiments of other investigators on the effects of asparagin are reviewed in some detail, and a series of experiments with sheep are reported. In each series 2 animals were used. In the first period of the first series the ration contained a limited amount of protein. In the second period asparagin was added to practically the same ration. In the second series the ration contained a limited amount of protein in the first period. In the second period ammonium acetate, and in the third asparagin was added to practically the same ration. In the first period of the third and fourth series the ration contained a medium amount of protein, and asparagin was added in the second period. The experimental data are recorded in full. The digestibility of the ration was determined in the different periods, and the balance of income and outgo of nitrogen.

In the first series the balance of income and outgo of sulphur was also determined, and was as follows:

Metabolism of sulphur in a ration with and without asparagin.—Experiments with sheep.

	Sulphur.			
	In food.	In urine.	In feces.	Gain (+), loss (-).
<i>Experiment 1.</i>				
Period 1 (without asparagin):	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>	<i>Gm.</i>
Sheep 1.....	1.807	0.927	0.878	+ 0.002
Sheep 2.....	1.781	.957	.834	- .010
Period 2 (with asparagin):				
Sheep 1.....	1.817	.849	.946	+ .022
Sheep 2.....	1.795	.805	.918	+ .072

In some of the experiments the urine was analyzed during the days which elapsed between the different periods. The results of the tests are discussed in detail. The principal conclusion reached is the fol-

lowing: When the ration contained an abundance of protein and was of a character which was suitable for production, asparagin generally exercised no favorable effect as regards gains in protein. When the ration was very deficient in protein, or when a maintenance ration containing little protein was fed and no work was done, asparagin exercised a beneficial effect as regards gains in protein, though the effect was small.

Methods of steer feeding, G. C. WATSON and M. S. McDOWELL (*Pennsylvania Sta. Bul.* 53, pp. 8; *Pennsylvania Dept. Agr. Bul.* 67, pp. 14).—This bulletin reports a cooperative experiment made by the station and the Pennsylvania Department of Agriculture. The comparative merits of feeding in pens and stalls was tested with 3 lots of 5 steers each, fed hay and corn stover in addition to a grain ration of corncob meal and wheat bran, 6:1. Lot 1 was fed in a large pen while the steers in lots 2 and 3 were confined in separate stalls. The steers in lot 1 were fed in a common manger and supplied with drinking water by means of an automatic water basin. The same device was used in supplying water to lot 2, while the steers in lot 3 were watered once a day in a yard adjoining the building where they were kept, one of the objects of the test being to study the effects of the different methods of supplying water. The average daily gain of the 3 lots was 12.16, 11.65, and 11.26 lbs., respectively.

"So far as any conclusions are warranted from a single experiment with a few animals, the above results would seem to indicate that dehorned steers can be fed in pens, in the manner practiced with lot 1, with at least as satisfactory results as regards gain as when handled in the more common way, while there is a very considerable saving in the amount of work required to properly care for them. The self-watering device also saved considerable work and possibly effected some economy in the amount of grain consumed per pound of gain, although the unavoidable differences between the lots render this conclusion far from certain."

Sheep-feeding experiments in Nebraska, E. A. BURNETT (*Nebraska Sta. Bul.* 66, pp. 16).—The value of different combinations of corn and other grains with alfalfa hay and prairie hay was studied. The grade lambs used in the test were divided into 3 lots of 16 animals, 4 of 8, and 1 of 20 each. After a preliminary period of 2 weeks on poor quality alfalfa hay and a light ration of shelled corn and oats the test began November 26, and covered 14 weeks. Lots 1, 2, and 3 were fed alfalfa hay and shelled corn, lot 2 receiving oats and lot 3 wheat bran, in addition. Lots 4, 5, 6, and 7 were fed shelled corn and prairie hay, lot 5 receiving linseed meal, lot 6 oats, and lot 7 wheat bran, in addition. All these lots were fed in sheds. For purposes of comparison, lot 8 was fed in an open yard, the same ration as lot 3. The gains ranged from 19 lbs. per lamb in the case of lots 6 and 7 to 34 lbs. in lot 8; the cost of a pound of gain from 2.2 cts. in lot 1 to 3 cts. in lots 5, 6, and 7. The greatest profit per sheep (\$2.05) was obtained with lot 1; the least (\$1.30) with lot 7.

"All the lambs were fed at a large profit notwithstanding [the] high original cost of 5 cts. per pound delivered at the farm. The alfalfa fed lambs consumed 1.34 lbs. of alfalfa hay and 1 lb. of grain per day as against 0.88 lb. of prairie hay and 0.89 lb. of grain consumed by the prairie hay fed lambs. The alfalfa fed lambs made 52 per cent greater gains than the lambs fed prairie hay with corn and the same grain ration. The lambs fed prairie hay with corn and 16 per cent of oil meal made 26 per cent larger gains than the lots fed prairie hay with a grain ration of shelled corn, or shelled corn with 25 per cent of bran or oats added. In these experiments the addition of bran or oats to the corn in the grain ration did not increase the gains, unless possibly in the case of the 20 lambs fed outside on alfalfa and corn with 25 per cent bran."

Roots and other succulent foods for swine, C. S. PLUMB (*Indiana Sta. Bul.* 82, pp. 93-105).—The value of succulent materials for the winter feeding of pigs is discussed and tests briefly reported on the use of sugar beets, artichokes and purslane for this purpose. When sugar beets were added to a ration of corn meal and shorts 1:2 a lot containing 4 pigs made an average daily gain of 3.89 lbs. during 98 days in the winter. Four similar pigs fed the same ration without beets made an average daily gain of 4.52 lbs. The cost of a pound of gain in the 2 cases was 3.2 and 2.93 cts., respectively. The author believes that the succulent foods have a beneficial influence on health which is not brought out by the results of the test.

To learn the value of artichokes, 4 sows were pastured on a small field planted with this crop for 2 weeks, being fed in addition corn meal and shorts (57.5 lbs. of each). The sows consumed practically all the artichoke tubers, the total gain in weight of the 4 animals being 27 lbs. The author believes better gains would have resulted on a larger field of artichokes. The feeding value of purslane was tested with 2 sows weighing not far from 160 lbs. each. In a period of 21 days they gained on an average of 18.8 lbs., at a cost of 2.2 cts. per pound. The ration consisted of shorts and hominy meal 1:1, with purslane *ad libitum*. About 9.25 lbs. of the latter was eaten per pig daily. Purslane "was not eaten with the relish that was to be expected; yet the pigs did very well while receiving it, making fair daily gains."

Bread and bread making at the Paris Exposition, H. W. WILEY (*Forum*, 30 (1900), No. 3, pp. 303-309).—The Schweitzer system of combined milling and baking is described.

Beans, peas, and other legumes as foods, MARY H. ABEL (*U. S. Dept. Agr. Farmers' Bul.* 121, pp. 32, figs. 10).—The composition, nutritive value, and digestibility of beans of different varieties, peas, lentils, peanuts, and some other legumes which are less common are treated of, as well as the place of legumes in the diet, the comparative value of a number of animal and vegetable foods, and similar topics. The bulletin is a summary of the available literature on the subject and also gives the results of practical experience and many experiments, some of which were undertaken in connection with the present work.

On the bacteriology of canned goods, with a detailed account of bacteria detected in sour corn, S. C. PRESCOTT (*Science*, n. ser., 11 (1900), No. 273, p. 442).—In a paper read before the Society of American Bacteriologists, 1899, investigations

were reported upon the bacteria present in cans of corn which had become spoiled and "swelled." The cause of the trouble was found to be the presence of certain species of bacilli which resisted the temperature used in canning the corn. The same bacilli were found upon the fresh corn and husks.

Food requirements in winter and summer in temperate climates, K. E. RANKE (*Ztschr. Biol.*, 40 (1900), No. 3, pp. 288-323, *figs.* 11).—Experimental investigations are reported in which the composition of food was determined as well as the amount of water consumed, and that excreted in the urine and feces, in winter and summer. The author's deductions follow: Above 16° C. there is no diminution in the amount of food required corresponding to the temperature. Physiologically active temperatures, which must exceed 20°, diminish markedly the appetite and therefore the food consumed, an effect which pertains more to pathology than to physiology. If large amounts are eaten contrary to the demands of the appetite, the pathological conditions become more marked.

Second report on dietaries for hospitals for the insane in the State of New York, W. O. ATWATER (*Reprint from Ann. Rpt. New York State Com. Lunacy*, 11 (1898-99), pp. 190-566).—Results of a large number of dietary studies of different groups of patients and employees in 2 of the New York State hospitals are reported. The work is discussed and some general deductions are drawn.

A manual of personal hygiene, W. L. PYLE (*Philadelphia: W. B. Saunders & Co.*, 1900, pp. 344, *figs.* 69).—This volume contains chapters on different hygienic topics contributed by a number of writers, that on hygiene of the digestive apparatus, being by C. G. Stockton.

Inspection of concentrated commercial feeding stuffs during 1900, W. H. JORDAN and C. G. JENTER (*New York State Sta. Bul.* 176, pp. 36).—Under the provisions of the State law regulating the sale of feeding stuffs, the protein and fat content of a number of concentrated feeds was determined. These included cotton-seed meal, oil meal, gluten meal and feed, calf meal, malt sprouts, dried brewers' grains, cereal food by-products, hominy feed, chop meal, sugar-corn feed, corn bran, boiled beef and bone, bone meal, beef scrap and meat meal, and a number of mixed proprietary feeds for stock and poultry.

Analyses of commercial feeding stuffs, J. L. HILLS, C. H. JONES, and B. O. WHITE (*Vermont Sta. Bul.* 82, pp. 59-79).—In carrying out the provisions of the State law regarding the inspection of commercial feeding stuffs, analyses are reported of 375 samples collected in the spring of 1900, including cotton-seed meal, linseed-oil meal, flax meal, gluten meal, gluten feed, cereal food by-products (*i. e.*, oat feed and corn and oat feeds), corn and oats, wheat bran, wheat middlings, mixed wheat feeds, corn-and-oat chop feeds, hominy feed, provenders, calf and poultry feeds, dairy feed, glucose bran, corn bran, barley bran, germ-oil meal, oil-cake germ meal, malted barley meal, malted corn meal, sifted corn meal, corn kernels, corn meal, potato feed, and ground oats.

The formation of mustard oil in rape-seed cake and its harmful effects, B. SJOLLEMA (*Landw. Vers. Stat.*, 54 (1900), No. 3-4, pp. 311-318).—Experiments on the poisonous properties of mustard oil and its formation in rape-seed cake are reported, as well as of the quantitative determination of mustard oil and the way of rendering cake containing it harmless.

The formation of glycogen when galactose is fed, E. WEINLAND (*Ztschr. Biol.*, 40 (1900), No. 3, pp. 374-385).—Experimental investigations are reported.

Principles and practices of stock feeding, J. L. HILLS (*Vermont Sta. Bul.* 81, pp. 56).—A popular summary discussing the principles of animal nutrition, quoting tables of feeding standards, the composition and digestibility of feeding materials, etc.

Cattle rearing in Egypt, C. M. BRUCE (*Jour. Khediv. Agr. Soc. and School Agr.*, 2 (1900), No. 4, pp. 176-181).—A general discussion, with especial reference to local conditions.

Feeding experiment with bullocks (*Bul. Agr. [London], Rpt. Agr. Education and Research, 1899-1900, pp. 42-44*).—A feeding experiment at the University College of North Wales to compare the value of maize meal and barley meal is briefly reported. As regards gains in weight, the rations tested were equally satisfactory. As regards the cost of food, there was a slight advantage in favor of the maize meal.

Feeding experiments, E. R. LLOYD (*Mississippi Sta. Rpt. 1900, pp. 20-34*).—The comparative value of corn, cotton seed, and cotton-seed meal; of cotton-seed hulls and cotton-seed meal; cooked and raw cotton seed; and peavine hay, Johnson grass hay, shredded corn and shredded sorghum, was studied. Twenty steers, divided into lots of 2 animals each, were used for these tests, which in every case covered 2 periods of 30 days each. According to the author, 1 lb. of cotton-seed meal was found to be equivalent to 1.81 lbs. of cotton seed, 1.67 lbs. of corn-and-cob meal, or 1.69 lbs. of cooked cotton seed. If cooked cotton seed is taken as a standard, 1 lb. is equivalent to 1.09 lbs. of raw cotton seed, 0.98 lb. of corn-and-cob meal, or 0.60 lb. of cotton-seed meal. One pound of peavine hay was found to be equivalent to 0.92 lb. of Johnson grass hay, 1.38 lbs. of shredded corn, or 1.78 lbs. of shredded sorghum.

Sheep-breeding experiments, J. R. CAMPBELL (*Bul. Yorkshire Col., Leeds, and East and West Ridings Joint Agr. Council, 1900, No. 13, pp. 8, dgm. 1*).—The results of breeding experiments with Lincoln and North Country ewes and Lincoln, Oxford, Hampshire, Shropshire, and Suffolk rams are reported.

Poultry foods and feeding, J. J. McCUE (*Agr. Gaz. New South Wales, 11 (1900), No. 9, pp. 770-779, fig. 1*).—A general discussion and a report of feeding tests with hens to compare dried blood, ox liver, and cut green bone when supplementing a ration of grain and green food. Both as regards egg production and financial returns, the lot having dried blood gave the best results.

Live stock; poultry, J. G. LEE (*Louisiana Stat. Bul. 62, 2. ser., pp. 447-453*).—Brief notes on the cattle, sheep, hogs, and poultry kept at the station and on chickens hatched with an incubator.

Index relating to animal industry, 1837 to 1898, G. F. THOMPSON (*U. S. Dept. Agr., Division of Publications Bul. 5, pp. 676*).—It is the purpose of this bibliography to include all literature relating to animal industry which has appeared in the publications of the United States Department of Agriculture since its inception in 1837, with the exception of the articles in the Experiment Station Record and Insect Life.

DAIRY FARMING—DAIRYING.

Sugar-beet pulp as a food for cows, H. H. WING and L. ANDERSON (*New York Cornell Bul. 183, pp. 16, dgm. 2*).—Sugar-beet pulp is described and an analysis of it given. Two feeding experiments are reported. The first was made with 5 cows and lasted 11 weeks, and the second was made with 6 cows and lasted 10 weeks. In the first test the same quantities of sugar-beet pulp and corn silage were fed to individual cows in alternate periods. A uniform grain ration was fed in addition. The cows were given more hay when fed pulp than when fed silage. In the second test more pulp was fed than silage, the quantities of hay and grain fed in addition being constant throughout. The results are given in detail in tables and diagrams, and the following conclusions are drawn:

“The cows, as a rule, ate beet pulp readily and consumed from 50 to 100 lbs. per day, according to size, in addition to the usual feed of 8 lbs. of grain and 6 to 12 lbs. of hay.

"The dry matter in beet pulp proved to be of equal value, pound for pound, with the dry matter in corn silage.

"The milk-producing value of beet pulp as it comes from the beet-sugar factory is about one-half that of corn silage.

"Beet pulp is especially valuable as a succulent food, and where no other such food is obtainable it may prove of greater comparative value than is given above."

The liability of the total solids of milk to change with age and its effect in the control of market milk, A. REINSCH and H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 3 (1900), No. 8, pp. 521-531).—From the examination of a considerable number of samples of milk when fresh and when 2 or 3 days old, it was found that the total solids diminished slightly with age, but that up to the time of souring the specific gravity did not change; hence the gravimetric result for solids in milk several days old would not agree with the result calculated by Fleischmann's formula, and if the gravimetric result alone were relied upon injustice might be done. Determination of the solids-not-fat is believed to be a more reliable basis for judging of the purity of milk, as this remains practically unchanged. Not until over 3 days after the sample has curdled does the specific gravity of the serum change sufficiently to make it unreliable.

Studies of the market milk of Helsingfors with special reference to its bacteria content, O. VON HELLENS (*Inaug. Diss., Helsingfors*, 1899, pp. 80; *abs. in Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 8, p. 261).—In summer the bacteria content ranged from 20,000 to 34,300,000 and averaged 474,500 per cubic centimeter; in winter the range was from 70,000 to 18,630,000, the average being 2,111,000 per cubic centimeter. There appeared to be a relation between the bacteria content and the dirt content of milk, although these did not vary regularly. A lower fat content was usually accompanied by a higher bacteria content. To a certain extent the acidity of the milk varied with its bacteria content.

The high germ content of the Helsingfors milk is believed to be due to lack of care in transporting the milk as well as in its production. Approximately one-third of the samples examined contained virulent tubercle bacilli. In 43 out of 57 samples other pathogenic bacteria were found, indicating that a large proportion of the Helsingfors milk contained two or more pathogenic germs.

Preservatives in dairy produce, G. S. THOMSON (*Jour. Agr. and Ind., South Australia*, 3 (1900), No. 12, pp. 969-981).—The use of boric acid and formalin in preserving milk is discussed. A table gives the results of a test of the relative keeping qualities of milk heated to 212 and to 185° F. for 10 minutes, raw milk, milk inoculated with germs of sewage water, and milk similarly inoculated but preserved with boric acid. Experiments are reported in detail in which milk preserved with boric acid was compared with unpreserved milk. Determinations were made of the acidity and specific gravity of the milk at different stages, and of the boric acid in the separator milk and

slime, and in the cream, butter, and buttermilk. Notes are given on the scoring and keeping qualities of the butter. The conclusions drawn from the tests follow:

"One and one-half tablespoonfuls of preservative, containing 82.5 per cent boracic acid, and added to 15 gal. of milk, showed a rise of 0.11 per cent acid in the milk at the end of 38 hours. In a similar quantity of milk, without a preservative, the percentage of acid rose 0.36 in the same number of hours. At the expiry of the 36 hours the preserved milk was faintly acid to taste, while the unpreserved milk was very acid.

"The percentage of acid and the specific gravity of the preserved milk were found to be lower at the top of the milk supply, when compared with the bottom, and proportionately lower than the unpreserved milk.

"Boracic acid gives to milk a liquefying property in the presence of a high percentage of lactic acid, similar with milk after sterilization by heat.

"Milk preserved with boracic acid may slowly rise in the percentage of acid, but it may suddenly increase to a high percentage in an abnormally short time.

"There accompanied the preserved milk, separator milk, and cream a faint bitterness which was not noted in the unpreserved samples.

"The boracic acid added to the milk was principally expelled in the separator milk in the process of separation.

"[Cream to which] 80 gm. of preservative was added . . . showed a rise of 0.08 per cent at the end of 69½ hours, while the unpreserved cream gave a rise of 0.23 per cent acid in the same number of hours.

"The boracic acid added to the cream was to a large extent removed in the buttermilk and washing water. . . .

"Milk preserved with boracic acid and the cream again preserved with additional acid will produce sweet unsalted butter of a low keeping quality, quickly affected with rancidity and bitterness.

"A pink mold will flourish in the presence of boracic acid in butter, when both the milk and cream have been preserved and when no salt has been added to the butter. . . .

"Bitterness accompanied the butter manufactured from preserved milk and cream when no salt was used in the butter, and the bitterness became exceedingly strong after a period of keeping. Butter with the salt and additional boracic acid did not develop the pronounced bitterness.

"The best keeping butter in the test proved to be the sample to which preservative was added to the milk, cream, and again to the butter, but the butter was salted at the rate of 3½ per cent."

Composition of butter made in the Netherlands and conditions which control the changes in composition, J. J. L. VAN RIJN (*Leyden*, pp. 12).—The study was undertaken because at certain seasons butter made in the Netherlands was rejected by the official English chemists as adulterated with "margarine or some other fat than butter fat." The English chemists based their conclusions upon the low percentage of soluble and insoluble fatty acids, while in the Netherlands the amount of volatile fatty acids present is considered the better criterion. The volatile fatty acids bear a nearly constant relation to the soluble fatty acids, being 89 to 95 per cent of the latter. The object of the study was to collect evidence to show that during the fall months the amount of volatile and of soluble fatty acids in the butter

made in the Netherlands is less than that which the English chemists accept as the minimum.

Samples of butter that had been churned under the supervision of the collector were taken weekly from 11 dairies and 13 creameries. These samples were tested, and it was found that in the late fall, shortly before the cattle were stabled for the winter, the amount of volatile fatty acids in the butter was much less than normal. Soon after the cows were stabled the amount of volatile fatty acid increased. It is thought that the warmth and comfort of the cows, due to stabling, accounts for the improvement in the butter, and that the practical remedy is the earlier stabling of the cows.—H. M. PIETERS.

The influence of certain conditions in churning on the amount of water in butter, J. B. WEEMS and F. W. BOUSKA (*Iowa Sta. Bul.* 52, pp. 43-53).—Investigations were made to determine the existence and effectiveness of some of the principles governing the proportion of water in butter. The relation of the size and shape of the granules to the water content of unworked butter and the removal of water by working are discussed.

In the experiments reported cream was ripened, cooled, and divided into 2 equal lots. Both lots in each test were churned under the same conditions in order to secure uniformity in the size and shape of granules. In each of 7 comparative tests one lot was washed with cold water and the other lot with comparatively warm water. The softer butter resulting from the use of the warmer water in washing contained the most water. In 3 comparisons where the granules were of the same size differences of 21, 24, and 32° F. in the temperature of the wash water made corresponding differences in the water content of the butter of 2.57, 2.66, and 2.30 per cent, respectively. In one test washing coarse granular butter with water at 45° was compared with washing fine granular butter with water at 70°. The water content of the butter made in the 2 ways was respectively 14.07 and 17.50 per cent. Several tests are also reported which showed that the extent of working influenced the water content of the butter.

These principles were observed in actual practice in preparing butter for export to England. The cream was churned at a low temperature and the churning continued until the granules were as large as peas. The butter was washed with cold wash water and given 2 partial workings. Of 32 samples analyzed, 24 contained less than 12 per cent of water.

The result of working on the water content of butter, J. SIEDEL and HESSE (*Milch Ztg.*, 29 (1900), Nos. 42, pp. 659, 660; 43, pp. 675, 676).—Butter from the same dairy was divided into 3 portions and treated as follows: (1) worked only a little and salted, (2) salted and left in the moist dairy as usual, and (3) salted and worked until it appeared to be very dry. The same amount of salt was added to each

lot. The butter was left until another day and worked once or twice until the water content appeared normal. The results were variable, but the average water content of the third portion averaged slightly higher.

The results also indicate that butter worked moderately when hard tends to hold on to its water content. To the old rule that soft butter should not be worked might be added that hard butter should not be worked until it becomes soft as it will become too poor in water.

The chemical action of molds on butter, J. HANUŠ and A. STOCKY (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 3 (1900), No. 9, pp. 606-614).—In preliminary experiments *Mucor ramosus* was found to grow best on butter, and this was used in subsequent experiments. In the latter it was found that the principal change was a cleavage of the glycerids, resulting in an increased acidity of the butter. From the fact that enzymes have been found in many molds the theory is suggested that the mold grows first on the nutrients it finds in the butter, *i. e.*, the carbohydrates and proteids, and when these are exhausted, elaborates the enzymes in large quantity which are capable of cleaving butter fat, and then feeds upon the glycerin liberated. The fungi appeared to be able to assimilate only such of the fatty acids liberated as are of low molecular weight.

Cream testing, C. H. ECKLES (*Iowa Sta. Bul.* 52, pp. 31-42).—The author discusses testing cream by the Babcock method, reporting several investigations in this connection and giving suggestions for avoiding common sources of error.

The influence of the thickness of sweet and sour cream upon the amount adhering to the pipette in measuring was tested. Cream was measured with a 17.6 cc. pipette when sweet and again after 24 hours. In one measurement in each case the pipette was blown out as in testing milk, and in one the adhering cream was rinsed out and added to the measured quantity. The results are given in the following table:

Comparison of two methods of measuring cream for the Babcock test.

Cream.	Pipette blown out.	Pipette rinsed out.	Gain by rinsing.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Fresh from separator.....	19.6	20	0.4
Sour, acidity 0.72 per cent.....	19.6	20.5	.9
Fresh from separator.....	29.8	30.4	.6
Sour, acidity 0.64 per cent.....	29.5	30.9	1.4
Fresh from separator.....	41.5	42.5	1
Sour, acidity 0.54 per cent.....	41	43.5	2.1

"From these figures it is evident no change in amount measured could be made to remove this varying error. This error can be removed easily and completely by rinsing out the pipette with about one-third of its volume of warm water and adding this to the measured cream."

Determinations were made of the error resulting from measuring the cream due to specific gravity, and a table designed for practical use is given showing corrections for different readings. Tests by measure of cream 5 hours and 24 hours after separation gave practically the same results. Determinations of the specific gravity of cream containing from 10 to 50 per cent of fat are given, and the method employed is described.

The source of separator slime, P. VIETH and M. SIEGFELD (*Molk. Ztg.*, 14 (1900), Nos. 42, pp. 725, 726; 43, pp. 746-748).—Analyses of separator slime made by various persons are quoted, together with the results of the researches of the writers. It was found that the milk richest in fat gave a greater amount of slime than poor milk, but the amount was not proportional to the fat content. The milk poorest in fat showed in the slime a smaller percentage of water and fat and a higher percentage of protein and ash.

From the results of their researches the authors conclude that, while not the only source, the serum capsule or envelope of the fat globule makes up the larger part of separator slime.

A study of butter increasers, J. B. WEEMS and F. W. BOUSKA (*Iowa Sta. Bul.* 52, pp. 54-59).—Two methods or recipes for increasing the yield of butter were investigated. Both are quoted, as well as a circular advertising one of them. The directions were followed in each case and the products obtained were analyzed. One method, in which sweet cream, sour cream, and butter were churned together, gave a product containing 41.54 per cent of water, 53.04 per cent of fat, 2.96 per cent of casein, and 2.46 per cent of ash. The butter scored 72½; it had no grain, and became soft and greasy a few minutes after taking from the refrigerator. The other method, in which sweet milk, butter, and a butter increaser consisting principally of alum and pepsin were used, gave a product containing 49.64 per cent of water, 41.46 per cent of fat, 5.06 per cent of casein, and 3.84 per cent of ash. It scored only 50, and besides having no body was of unsatisfactory flavor. "The butter increaser had curdled the milk and also spoiled the flavor." Two samples of a similar product received from firms in Chicago showed 59.61 and 42.76 per cent of water and 21.31 and 44.92 per cent of fat, respectively. One had 11.72 per cent of casein. Another process recently patented in England is described.

Dairy husbandry, J. S. MOORE (*Mississippi Sta. Rpt.* 1900, pp. 25-33).—Notes are given on the feeding and care of the station herd of pure-bred Jersey cows. A monthly summary of the yield of milk, average fat content of milk, yield of butter, and the cost of feed for each of the 8 cows in the herd is given in tables. The average production per cow for the year was 5,192 lbs. of milk containing 5.52 per cent of fat and yielding 334.4 lbs. of butter. The cost of feed was \$29.57.

An experiment lasting 12 weeks was made to test the effect of feeding grain to cows on pasture. The herd was divided into 2 lots, both of which were fed grain during

the first 6 weeks of the test. During the last 6 weeks only one lot received grain. The results were considered as showing practically no difference in the yield of milk due to feeding grain to cows on good pasture.

The relative values of mangels and swedes as food for dairy cattle, W. P. J. ALLSEBROOK (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), No. 3, pp. 163-168).—A study of the relative cost of production, feeding value, and value of the residue. Tables of analyses are compiled. From most points of view the mangel is considered the more valuable crop to the dairy farmer.

The use of the cactus *Opuntia ficus indica* in a ration for milch cows in Sardinia, G. SOTGIA (*Staz. Sper. Agr. Ital.*, 33 (1900), p. 113; *abs. in Centbl. Agr. Chem.*, 29 (1900), No. 12, pp. 803, 804).—An analysis showing the feeding value of the plant is given and the results of its use as a part of a ration for milch cows are reported.

The effect of gestation in cows upon the mineral matter of milk, especially phosphoric acid and lime, A. KORT (*L'Ing. Agr. Gemblour*, 9 (1899), pp. 453-475; *abs. Centbl. Agr. Chem.*, 29 (1900), No. 10, pp. 667, 668).—It was found that the percentage of phosphoric acid and lime decreased more or less regularly up to the time of calving, while the colostrum was rich in ash. When lactation was greatest the percentage of phosphoric acid and lime was lowest, the amount increasing and remaining at the normal up to the middle portion of the next gestation period. The food had no influence upon either the mineral content of the milk or of the urine of cows.

The handling of milk samples, M. SIEGFELD (*Molk. Ztg.*, 14 (1900), No. 46, pp. 797-799).—Rules for taking and keeping milk samples are given.

Bacteriology of milk, B. H. STONE (*Amer. Cheesemaker*, 15 (1901), No. 179, pp. 1, 2).—A paper read at the Vermont Dairymen's Association by the State bacteriologist.

Improvements in cream testing, A. C. BEBEE (*Chicago Dairy Produce*, 7 (1901), No. 71, p. 22).—Conclusions reached by daily experiments long conducted, upon the influence of speed, temperature, and time whirled and the scaling and marking of bottles in the Babcock test.

Tyrogen, a pure culture of ripening bacteria of Emmenthaler cheese, W. WINKLER (*Molk. Ztg.*, 14 (1900), No. 47, pp. 817, 818).—A pure culture of *Bacillus nobilis*. The advantages in using a pure culture of this bacillus are said to be improvement in the form and construction of the cheese, the imparting of a uniform Emmenthaler taste and aroma, and the shortening of the process of manufacture.

The use of the acidimeter in cheese making, MARGARET KNOWLES (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), No. 1, pp. 37-40).—A popular article describing the method or making the acid test of milk, and stating its advantages over the rennet and hot-iron tests.

VETERINARY SCIENCE AND PRACTICE.

Communications from the official veterinary sanitary reports for the year 1898, J. ESSER and W. SCHÜTZ (*Arch. Wiss. u. Prakt. Thierh.*, 26 (1900), Nos. 4-5, pp. 336-388).—In one locality a number of outbreaks of anthrax occurred after eating beet chips. The beets had been grown in a territory known to be infected with anthrax. In another locality several head of cattle were affected with anthrax after feeding with green corn which had been grown in an anthrax territory. Outbreaks of anthrax were also caused by dusting stalls with soil taken from the vicinity of anthrax carcasses, and using gravel from a similar

locality about sheep corrals. A few cases of spontaneous recovery from the apoplectic form of anthrax are recorded. Preventive vaccination against blackleg gave good results in 600 young cattle. A detailed report is made on the prevalence of rabies. In the case of a horse which was bitten by a rabid dog, an incubative period of 21 months was noted. Notes are also given on foot-and-mouth disease, pneumonia, and glanders. Foth's mallein was used in the study of an epidemic of glanders. Two horses which gave no reaction to the first injection manifested symptoms of glanders 17 days later, and of 8 horses which gave a typical reaction, only 2 proved to be infected with glanders.

Brief accounts are given on the prevalence of tuberculosis and hog cholera. The average cost of applying the Lorenz vaccination method for hog cholera was about 12 cts. The vaccination had no injurious effect upon the hogs. In a number of localities where hog cholera had caused annual losses of considerable severity, this disease was apparently eradicated by vaccination. Brief notes are also given on cowpox, actinomycosis, mineral and plant poisoning, organic diseases, and meat inspection.

Texas fever in the Argentine Republic, LIGNIÈRES (*Rec. Méd. Vét.*, Paris, 8. ser., 7 (1900), No. 22, pp. 735-774, figs. 3).—In Argentina and Uruguay this disease is known by the name of "tristeza." The author presents a critical review of the literature of the subject and describes in detail the symptoms and post-mortem conditions in the mild and acute cases of the disease. During the author's studies, especial attention was given to alterations in the blood and urine of diseased animals. From these investigations it was found that the blood parasite of Texas fever exerts an influence especially upon the hemoglobin and albumin of the blood, destroying a considerable part of the former with fixation of iron, and rendering both the hemoglobin and albumin more soluble. The quantity of sugar preformed in the blood remains about stationary, while the glucosids and the proteid materials undergo a rapid diminution. It was found also that the blood of diseased animals when taken during the acute stage of the disease, was extremely irritant and toxic. Such blood when injected into the marginal vein of the ear of a rabbit in doses of from 3 to 5 cc., killed the animal within a few seconds. The same quantity of blood injected into the peritoneum of the guinea pig produced death within a few minutes. The symptoms of death in such cases were those caused by caustic fluids. After the hemoglobinuric stage had passed, the blood remained light colored for a long time and slowly recovered its normal properties. In such cases the blood of diseased animals, although pale when in the vessels, assumes a reddish color on exposure to the air. This fact was observed when the destruction of the red corpuscles was relatively slight. A few hours before death it was noted that the blood had nearly the color of coffee.

The author made a detailed study of alterations in the structure of the red blood corpuscles during the various stages of the disease. Notes are also given on the diminution of the number of red corpuscles.

The whole subject of the development of *Pyrosoma bigeminum* is reviewed in detail by the author. It is stated that all pyriform hematozoa assume a round form at one stage, and that this is a natural and not merely an accidental form in the development of the parasite. The round form was found in the organism in considerable abundance, especially when the disease began to decline. In no case did the round form become metamorphosed directly into a pyriform hematozoön.

The author succeeded in following the development of the blood parasite of Texas fever in artificial cultures, and in connection with the known fact of the existence of both a mild and an acute form of the disease, raises the question as to whether these two forms of the disease may be due to two forms of the blood parasite.

Parturient apoplexy under Schmidt's treatment, J. H. TENNENT (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 5, pp. 286-292).—The author applied Schmidt's treatment in the following manner: A quart of boiling water was poured into a clean vessel and when cooled to a temperature of 100° F., 1 dram of formalin and 1½ drams of potassium iodid were added and the whole was gently shaken. The cows which were to be treated were thoroughly milked and the udder and teats were washed with antiseptic solutions. Eight ounces of the solution of formalin and potassium iodid in water were injected into each quarter of the udder through the milk ducts of the teat. Treatment which accompanied the use of Schmidt's treatment consisted in the removal of feces from the rectum and the use of a catheter in cases where urine was retained over 12 hours. No medicines were given by the mouth unless the patient was able to stand. Detailed notes are given on the history and treatment of 15 cases of parturient apoplexy, of which 13 recovered and the author believes the other 2 cows would have recovered but for the interference of the owners. Some of the worst cases made the most speedy recovery. Considerable difficulty was experienced in keeping up the heart's action, but this was successfully accomplished by the use of nux vomica and whisky.

A preliminary report upon forage poisoning in horses (so-called cerebro-spinal meningitis), L. PEARSON (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 11, pp. 654-657).—The author investigated an outbreak of disease among 7 horses of which 5 died. The symptoms were those of paralysis, which affected the throat first and gradually extended to other parts of the body. Two of the 7 horses which were removed from the barn ultimately recovered. A silo had been opened about a week before the first cases were noticed, and as the silage was moldy on top it was suspected of causing the trouble. The author therefore conducted 2 feeding experiments with this silage. Between October 30 and November 2, 1900, a horse was given approximately

$\frac{1}{2}$ bu. of the silage mixed with oats and bran. On November 3 there was a well marked paralysis of the throat and a slight elevation of temperature. The general muscular weakness progressed until the horse was unable to stand. Death occurred November 4. Another horse was given 4 gal. of water which had percolated through a bushel of silage on November 5, 3 gal. on November 6, and on November 8 he was given 6 qt. of silage. Similar symptoms were developed and on November 10 the animal was found dead. The author believes that cerebro-spinal meningitis is an inappropriate term for this disease and proposes the name forage poisoning.

The action of certain somnifacients on the horse, E. S. MUIR (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), Nos. 4, pp. 193-198; 5, pp. 278-282).—The author conducted a number of experiments for the purpose of determining the action of sulphate of morphia, normal liquid *Cannabis indica*, and chloral hydrate crystals upon the horse. From his experiments it was evident that sulphate of morphia produces more or less delirium in the horse, while occasionally a slight delirium followed the administration of large doses of *Cannabis indica*. The pupils become widely dilated after large doses of morphia, while *Cannabis indica* has no action in that direction. The only pronounced action of chloral was somnolence, accompanied by a muscular weakness. The author gave 60 cc. of *Cannabis indica* intravenously without producing any alarming symptoms, and it is believed that with a horse of 1,100 lbs. weight in good condition, it would be quite safe to inject into the jugular vein 1 gm. sulphate of morphia, 50 cc. of *Cannabis indica*, or from 25 to 30 gm. of chloral hydrate.

Experimental studies of rabies, VERA SOLOMON (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 3, pp. 70-79, figs. 3).—The author conducted experiments in devising new methods for the experimental diagnosis of rabies and in determining the action of the bile upon the virus of rabies. The virulent materials for experimental inoculations which have thus far been applied include the saliva of man or of a rabid animal, the salivary glands, kidneys, pancreas, milk, and central nerve substance, especially the medulla oblongata. The different methods thus far employed for experimental diagnosis are intracutaneous injection, subcutaneous injection, infection of the mucous membrane of the nose, inoculation of the serous membranes, inoculation of the chambers of the eye, subdural injection, inoculation of the nervus medianus, intravenous inoculation, intracerebral inoculation, and inoculation in the lumbar portion of the spinal cord.

The author experimented with these different remedies, and especially upon different methods of intracerebral inoculation. The method devised by Leclainche and Morel is considered by the author more satisfactory than that of Pasteur and Roux for the reason that it is cheaper, more easy of application, and more certain in its results.

Experiments were also tried in experimental diagnosis of rabies by means of direct inoculation through the occipital foramen. This method gave good results and is considered satisfactory and unobjectionable, except for possible accident which might result from the sudden movement of the animal.

The author undertook a series of experiments on rabbits for the purpose of determining the effect of bile upon rabies virus. The active virus and bile were taken from rabbits just dead of rabies, mixed in equal parts, and inoculated in the subdural region. The results of these experiments indicate that pathological bile renders the incubation period of rabies longer, and in certain cases neutralizes the virus, while normal bile has a similar though much weaker action.

Hemorrhagic septicæmia of ducks and chickens, A. RABIEAUX (*Jour. Med. Vet. et Zootech.*, 5. ser., 4 (1900), pp. 129-140, fig. 1).—An epizootic occurrence of this disease was observed in November, 1899, among a number of poultry establishments in one neighborhood. The ducks and chickens were receiving at the time as food grain and potatoes. The outbreak of the disease was sudden, 36 cases having developed within 14 hours, of which 18 were among ducks and 18 among chickens. Sixteen of the ducks and 14 of the chickens succumbed to the disease. An autopsy made upon some of the dead birds showed little or no pericardial exudate. There were numerous confluent ecchymoses upon the heart and the mucous membrane of the small intestine was thickened and much congested. The contents of the intestine were bloody. The clinical symptoms were not constant nor well marked. As a rule, the progress of the disease was so rapid that the symptoms were not observed. In some instances the author observed a staggering gait in the birds shortly before death. The pathogenic organism of this disease was an ovoid bacterium which resembled that of chicken cholera, but was slightly larger. The organism was found in abundance in the blood, liver, spleen, bone marrow, and intestinal contents. When examined fresh, the organism appeared to be a coccus or diplococcus with active brownian movements. It was readily stained with Kühne blue or carbolized thionin. After being stained, the organism appeared in the form of a bacillus with rounded ends.

The organism is aerobic and can be cultivated easily upon all the ordinary media at a temperature of from 35 to 38° C., except upon potato. In artificial media and in contact with the air, an attenuation of the organism progresses rapidly with a complete loss of its virulence in from 15 to 30 days. The organism has only a slight resisting power to desiccation or to the ordinary antiseptic reagents. It is very susceptible to heat and is destroyed by exposure for 6 minutes to a temperature of 55 to 56° C. Cultures of the organism in bouillon heated to 60° C. and then filtered lose all their virulence, but the filtrate con-

tains a toxin which produces an elevation of temperature and other symptoms when inoculated in rabbits and other laboratory animals. The toxin appears to be exceedingly active, especially when inoculated into the jugular vein.

The disease can be transmitted experimentally either with pure cultures, with isolated bacteria, or with material collected from animals dead of this disease. In ducks and chickens the disease can be produced by ingestion of pure cultures or virulent products mixed with food. Death occurs in from 30 to 48 hours after eating such material. The post-mortem appearances in these cases are exactly the same as in cases of death resulting from the disease when acquired under natural conditions. The rabbit was found to be most susceptible and the guinea pig most resistant to inoculations with this organism. By passing the organism repeatedly through a series of experimental animals belonging to the same species, its virulence is increased for this species. By passing this organism through rabbits, it was observed that its virulence was decidedly increased for the rabbit, but was not especially modified as regards the pigeon, and was attenuated as regards its action upon guinea pigs. Repeated inoculation of sterilized cultures into rabbits and guinea pigs conferred immunity upon these animals to the disease.

The author believes that this disease should not be confounded with chicken cholera. It differs from chicken cholera, especially in the susceptibility of different animals to the organism. The pathogenic agent of the disease is an ovoid bacterium which seems to have acquired an unusually high virulence.

The epidemiology of malaria from recent observations, A. CELLI (*Contrib. Bakt. u. Par., 1. Abt., 28 (1900), No. 17, pp. 530-535*).—The author found that the distribution of malaria-bearing mosquitoes was more extensive than that of the disease. The various species of mosquitoes may be carried in different ways to considerable heights on mountain sides or into other localities where malaria does not prevail. Brief notes are given on the distribution of *Anopheles claviger*, *A. pictus*, *A. pseudo-pictus*, and *A. bifurcatus*.

Entozoa, A. E. SHIPLEY (*Fauna Hawaiensis, 2 (1900), No. 4, pp. 427-446, pls. 2*).—The author gives brief notes on the parasitic worms found in the domestic animals and man in the Sandwich Islands.

A text-book of special pathology and therapy of domestic animals, F. FRIEDBERGER and E. FROHNER (*Lehrbuch der speciellen Pathologie und Therapie der Haustiere. Stuttgart: Ferdinand Enke, 1900, vol. 2, 5. ed., pp. 756*).—This volume contains chapters on the following subjects: Diseases of the nasal cavity; diseases of the larynx; diseases of the trachea, bronchial tubes; lung diseases; diseases of the pleura; chronic constitutional diseases, and contagious diseases in general.

Bacteriological and pathological microscopy, T. KITT (*Bakterienkunde und pathologische Mikroskopie für Thierärzte und Studierende der Thiermedizin. Vienna: M. Perles, 1899, 3. ed., pp. 525, pls. 2, figs. 155*).—This volume contains an account of technical methods for the study of pathogenic bacteria; preparation of sections of pathological tissue; methods of inoculation of experimental animals; methods of

studying parasitic insects, mites, and worms, and a general account of the bacteria which cause the common infectious diseases.

The histology of the spleen during the course of infectious diseases, DOMINICI (*Arch. Med. Exper. et Anat. Path., Paris, 1. ser., 12 (1900), No. 6, pp. 733-768, pls. 3*).—The author conducted experiments for the purpose of determining the rôle of and anatomical changes in the spleen during an infection of septicæmia caused by the bacillus of Eberth. It was found that the spleen under such conditions fulfills the function of producing leucocytes and giant phagocytes. During the process of the disease the spleen underwent a myeloid transformation.

The germicide and agglutinating properties of serums immunized against *Bacillus pyocyaneus*, P. MÜLLER (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 18, pp. 577-587*).—From experiments made outside of the animal organism, the author concludes that in the absence of oxygen the germicide power of the normal serum of guinea pigs toward *B. pyocyaneus* is greater than in the presence of oxygen. Non-virulent bacteria were much checked in their growth by a normal serum, while virulent forms were not especially affected. Serums which were immune to *B. pyocyaneus* exhibited a stronger germicide power under aerobic conditions than normal serum.

Agglutination of the *Trypanosoma* of the rat upon different kinds of serum, LAVERAN and NESNIL (*Compt. Rend. Soc. Biol. Paris, 52 (1900), No. 34, pp. 939-942*).—The author tested the action of the serum of different animals in agglutinating *Trypanosoma*. Rabbits, dogs, sheep, horses, chickens, pigeons, and rats were used for this purpose. The sera of all these animals, except that of the rat, agglutinated the *Trypanosoma* within a period of an hour, when mixed with an equal volume of defibrinated blood containing these parasites. The *Trypanosoma* was not immobilized before it became agglutinated.

Intravenous injection of potassium iodid and protargol, PETER (*Berlin. Tierärztl. Wehnschr., 1900, No. 33, pp. 385-387*).—The author experimented with intravenous injections of protargol in the treatment of a number of cases of morbus maculosus. It was found that a single dose of 100 gm. of a 75 per cent aqueous solution of protargol could be injected into the blood of cattle and horses without injurious effects, and that a noticeable therapeutic effect was produced by this substance in the treatment of malignant catarrh of cattle. Potassium iodid was used in combination with proteids. The results of the author's experiments indicate that this substance may be safely used in intravenous injections. An experiment with sodium iodid combined with proteids on the other hand demonstrated that this substance is not suitable for intravenous injections, since serious disturbances were produced in the red blood corpuscles which resulted in a hæmoglobinuria.

Treatment of tetanus by fright, KISSUTH (*Berlin. Tierärztl. Wehnschr., 1900, No. 45, p. 532*).—Two cases of undoubted tetanus were treated by fright produced by firing a gun in the stall in which the affected horses stood. The gun was fired at the time when the muscular contraction was at its height, and had the effect of producing a complete muscular relaxation, after which the animals were able to eat and drink without much difficulty. One case recovered completely after a period of 14 days, while recovery in the other case was slower.

Report of veterinarian, J. C. ROBERT (*Mississippi Sta. Rpt. 1900, pp. 36-40*).—The work of the year on Texas fever consisted chiefly in an attempt to determine the value of blood inoculation in preventing the appearance of disease in southern cattle and the discovery of some efficient curative agent. Twenty-five young northern cattle were inoculated with blood from tick-infested native cattle. The amount of blood used varied from 1½ to 5 cc. and was used in some cases as drawn and in other cases defibrinated. Symptoms of inoculation fever appeared within 10 days. None of the animals died and they were turned out with native cattle about 5 weeks after the second inoculation. Southern cattle frequently die of Texas fever. Some cattle

appear to escape tick infestation while young, and when they subsequently become infested with large numbers of ticks they succumb to the virulent form of the disease. The only treatment from which the author obtained any favorable results consisted in administering 1 lb. of Epsom salts and hypodermic doses of 30 grains of quinine every 3 hours. Brief notes are given on the occurrence of blackleg, anthrax, glanders, and tuberculosis in the State.

List of plants of known or suspected poisonous properties which occur within the State, E. V. WILCOX (*Montana Sta. Bul. 22, pp. 51-53*).—A list is given of 14 species of plants which are known to the writer as being poisonous, or which have been suspected by stock growers as being injurious to stock. Of the species mentioned the purple and tall larkspurs, aconite, lupine, death camass, nightshade, and water hemlock are known to have caused the death of a number of animals, and loco weeds are suspected as being injurious. The author investigated a number of cases of poison reputed to be due to certain plants, but upon investigation found that the evidence was either of a very unsubstantial nature, or the suspected plant was in no way connected with the death of the animals.

Lupines as plants poisonous to stock, E. V. WILCOX (*Montana Sta. Bul. 22, pp. 37-45*).—Brief notes are given on a number of cases of poisoning from lupine which were observed in Montana. In 1 case 100 out of 200 bucks fed upon lupine hay died within a few hours after feeding. In another case a considerable loss of sheep was suffered from allowing them to eat ripe lupine upon the range. After autumn snowstorms in 1898 the loss of sheep from eating lupine upon the range in Montana amounted to 2,000, 1,150 of which were from 1 band. A few cases of lupine poisoning in horses are also recorded. The most severe losses from lupine poisoning have been due to eating these plants in the form of hay, a large quantity of which is annually cut in the State. The poisoning in all cases seemed to be due to eating the ripe or nearly ripe seed, which would appear to contain the poisonous principles in greater abundance than other parts of the plant. A brief bibliography is also given.

Cattle poisoning by the tall larkspur, E. V. WILCOX (*Montana Sta. Bul. 22, pp. 45-47*).—Notes are given on the appearance and distribution of *Delphinium glaucum* in Montana. An outbreak of cattle poisoning which occurred in the Gallatin Basin, and which resulted in the death of 40 cattle, was investigated. It was found that the poisoning was due to the species of larkspur just mentioned, and that this plant had been apparently eaten in unusual quantities, on account of the fact that other green forage was covered by a recent fall of snow.

Poisoning of stock by the water hemlock, E. V. WILCOX (*Montana Sta. Bul. 22, p. 48*).—Brief notes on cases of poisoning from this plant in man, sheep, and cattle. In cattle the symptoms were severe pain, accompanied by cerebral excitement and spasms. In 1 case the animal died within 15 minutes after the appearance of the first symptoms.

The poisoning of cattle by smutty oat hay, E. V. WILCOX (*Montana Sta. Bul. 22, p. 51*).—During the winter of 1898 a dairyman lost 12 cows in feeding smutty oat hay. The oats had become so badly smutted that they were cut for hay rather than grain. Out of 30 cows which received 1 feed of the smutty oat hay 12 died within 18 hours after feeding, with symptoms of gastric disturbances and cerebral excitement.

Ergotism in horses, E. V. WILCOX (*Montana Sta. Bul. 22, pp. 49, 50*).—Ergot is reported as very abundant on a considerable variety of native grasses in the State. A number of cases of poisoning observed in horses are believed to be forms of ergotism. The symptoms were a gradual paralysis beginning with the muscles of the throat; horses were soon unable to swallow, and later became unable to stand, and died of general paralysis. Death occurred in the majority of cases within from 6 to 12 hours. In 2 cases recovery took place after the administration of strychnin hypodermically and whisky by the mouth.

Report of the veterinary service and meat inspection in Norway for the year 1898 (*pp. 126*).—This report contains a general account of the work of the veterinary department, together with special accounts of anthrax, catarrhal fever, blackleg, hog cholera, swine plague, tuberculosis, milk fever, and other diseases. The regulations for meat inspection in different cities are also given, together with notes on the frequency of various diseases found during such inspection.

The diseases of cattle, D. MONFALLET (*Bol. Soc. Nac. Agr. [Lima], 5. ser., 1900, No. 1, pp. 35-53*).—The author gives a general account of the various forms, etiological symptoms and treatment of pneumonia and pleurisy in cattle.

Actinomycosis in cattle, C. J. REAKES (*Veterinarian, 73 (1900), No. 871, pp. 357-359*).—The author presents an account of an unusual outbreak of actinomycosis in Ellsmere.

Anthrax, KISSUTH (*Berlin. Tierärztl. Wehnschr., 1900, No. 46, p. 543*).—Among 60 head of cattle, which were shipped to Gurhau from eastern Prussia, 4 developed acute cases of anthrax within a few hours after being turned out to pasture, and 3 died. The author believes that anthrax spores were taken on the food, and that the action was more rapid and more severe on account of the empty condition of the digestive tract.

A variety of anthrax bacillus with short forms and without spores, C. PHISALIX (*Compt. Rend. Acad. Sci. Paris, 131 (1900), No. 7, pp. 424-427*).—A number of forms of this organism have already been noted and have received different names. These different forms are found under different conditions or in the blood of different animals. In the dog the anthrax bacillus undergoes important modifications, the first of which are changes in its functions and virulence. The bacillus multiplies rapidly by budding and the formation of short rods similar to micrococcus. The name *Bacillus anthracis brevigenmans* is proposed for this form.

Agglutination of the tubercle bacillus by tuberculous serums, P. COURMONT (*Compt. Rend. Soc. Biol. Paris, 52 (1900), No. 36, pp. 1000-1002*).—The author obtained positive results in experimental tests of such serums from man and animals, and believes that this method constitutes a rapid and certain procedure for diagnosing tuberculosis. Experiments with nontuberculous discharges of diphtheritic or septicaemic nature gave negative results.

An experiment in the transmission of tuberculosis, E. PERRONCITO (*Gior. R. Soc. Accad. Vet. Ital., 49 (1900), No. 45, pp. 1057, 1058*).—The author fed 2 pigs with milk to which had been added fresh tuberculous material of bovine origin. Generalized cases of tuberculosis were developed in both experimental animals.

Tuberculosis in New Zealand, J. A. GILRUTH (*Veterinarian, 73 (1900), No. 870, pp. 359-370*).—Notes on 1,500 tuberculin tests, chiefly in dairy cows. The author discusses general infection, the means by which the disease is spread, the method of extermination, and regulations for controlling the prevalence of the disease. The author believes that tuberculin has no curative action upon tuberculosis.

Tuberculosis in pheasants in Wangamui, S. H. DREW (*Trans. and Proc. New Zealand Inst., 32 (1899), pp. 54-56*).—The Wellington Acclimatization Society imported a number of *Phasianus reevesii*. The birds were inclosed for a time after arrival in a pen near a museum. After some time one of the birds died, and on making a post-mortem examination it was found that various vital organs were badly infected with tuberculosis. Similar experience was had by other societies in importing these birds. It remains doubtful how the birds became infected, since they were watered with rain water and were fed no meat, liver, or milk. The only other animals which could enter the inclosure were rats, and it is suggested that the infection may have been carried by them.

On the behavior of the tubercle bacillus in frogs, O. LUBARSCH (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), Nos. 14-15, pp. 421-430*).—This is mainly a controversial article, but from additional experiments made by the author it is concluded that

tubercle bacilli introduced into the lymph cavity of a frog are carried from this position into the internal organs and may be found in such locations for weeks or even months. At the point of injection small granulating tubercles are not infrequently developed. Tubercle bacilli which have remained for weeks in the body of a frog do not produce tubercles when inoculated into guinea pigs.

Parturient apoplexy. A discussion of milk fever, W. A. THOMAS (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 11, pp. 671-675).—In order to secure information regarding the methods of treatment of practicing veterinarians and their success with cases of parturient apoplexy, the author sent out a circular letter of inquiry to the practicing veterinarians of Nebraska, from whom 11 replies were received. Of the veterinarians who replied to the circular 9 had given medicine by way of the mouth and 3 had adopted the Schmidt treatment. The success of treatment was not striking in any case. The author objects to the use of the term parturient paresis and inclines to the belief that the primary lesions of the disease are in the brain.

Tumor formations in certain of the domestic animals, J. A. GILRUTH (*Veterinarian*, 73 (1900), No. 870, pp. 291-301, figs. 6).—Degenerate and calcified hydatids were present in the lungs and liver of a vast majority of cattle and sheep inspected in the abattoirs of New Zealand. Notes are given for the purpose of reaching a differential diagnosis between such nodules and those of tuberculosis. A similar discussion is given of nodules of the peritoneal surface of the intestines, calcareous nodules in the flanks of sheep, epithelioma, and granuloma.

Swine fever, J. A. GILRUTH (*Veterinarian*, 73 (1900), No. 872, pp. 419-439, figs. 4).—From a series of observations and experiments made by the author it is concluded that pulmonary and pleural lesions frequently occur along with or independently of the so-called characteristic intestinal lesions of swine fever. The results obtained indicate that it is doubtful whether hog cholera and swine plague are 2 distinct diseases.

Mallein in the treatment of glanders, J. McCALL (*Veterinarian*, 73 (1900), No. 870, pp. 383-387).—Detailed notes are given on 4 horses injected with mallein. Cultures made from tubercles found on post-mortem examination gave negative results, while the reaction to mallein was well marked, and the usual anatomical lesions of glanders were found.

The nature of "horse sickness," RICKMANN (*Berlin. Tierärztl. Wehnschr.*, 1900, No. 29, pp. 337, 338).—The author inoculated himself and also a horse with 1 cc. of virulent blood from a case of this disease. After 11 days the horse died of typical symptoms of the disease, while the author was entirely unaffected by the operation, although he was susceptible to malaria. The author believes that although this disease is very similar to malaria it is not identical with it.

Diseases caused by horse worms, and their treatment, F. V. THEOBALD (*Jour. Southeast Agr. Col. Wye*, 1900, No. 9, pp. 49-66, figs. 7).—Biological and economic notes are given on the common species of tapeworms and nematodes, which are found parasitic in the horse.

Dourine and its pathogenic organism, G. SCHNEIDER and M. BUFFARD (*Rec. Med. Vet.*, Paris, 8. ser., 7 (1900), No. 3, pp. 81-105, figs. 20).—The authors made extended investigations on dourine in horses with regard to methods of prevention, diagnosis, and treatment, and a special study of the etiology of the disease. The pathogenic organism is considered to be a species of *Trypanosoma*. The authors were able to produce the disease experimentally in horses, dogs, rabbits, rats, mice, and the jackass. It was found that the organism could be transmitted by a hypodermic injection, by contact with the mucous membrane of the vagina, and by inoculation under the cerebral membranes.

Detailed notes are given on the period of incubation of the disease in different

animals and upon the symptoms and course of the disease. The pathogenic organism is described and figured.

A diagnosis of rabies, H. VALÉE (*Rev. Vet. Toulouse*, 25 (1900), No. 12, pp. 761-768).—A brief critical discussion of the various methods which have been proposed for diagnosing rabies before and after death.

Diagnosis of rabies upon an histological examination of nerve centers of animals which have died prematurely, C. FRANÇA (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 36, pp. 985-987).—From microscopic post-mortem examinations made by the author it is concluded that rabid animals which die prematurely do not always exhibit the rabic nodules in the ganglia. More frequently it was found that such elements exist only in an extra capsular position in a greater or less quantity. Lesions in the bulb were more striking and were formed earlier than those in the ganglia.

Rabies in dogs, I. GUERRICABEITIA (*Gac. Med. Vet.*, 24 (1900), No. 174, pp. 513-516).—Brief notes by way of diagnosis of this disease.

Common diseases of the fowls—their control and treatment, F. D. CHESTER (*Delaware Sta. Bul.* 47, pp. 30, figs. 12).—This bulletin contains a general account of the common diseases of poultry. The author discusses the symptoms, etiology, and treatment of gapes, simple catarrh, roup, pip, noninfectious gastroenteritis, fowl cholera, asthenia, blackhead, various diseases of the reproductive organs, vertigo, epilepsy, scaly leg, depluming scabies, favus, bumblefoot, tuberculosis, and infectious leukæmia.

Roup of chickens, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 27-29).—A brief description of the disease and an account of the remedies usually adopted against this disease are given. During an outbreak of roup in Montana diphtheritic membranes were removed from the mouth and larynx and a direct application of lunar caustic was then made to the raw surface thus exposed. The mouth cavity and eyes were then washed with a solution of nitrate of silver in the proportion of 8 grains to the ounce of water. In some cases 1 application was successful, while in others 2 or 3 were required.

The internal chicken mite, E. V. WILCOX (*Montana Sta. Bul.* 22, pp. 30-36).—A brief description of *Cytodites nudus* is given and the literature relating to this species is discussed. While studying this mite in Montana it was found in 5 chickens which were evidently suffering from some serious disease. In 1 case a large number of intestinal nematodes were present and in the other 4 cases the chickens were affected with nodular teniasis. Two perfectly healthy chickens were found to be thoroughly infested with cytodites, and in these cases, as well as in the others, no lesions were traceable to the action of cytodites. Thorough disinfection of poultry houses is recommended as a preventive measure against this mite.

Intestinal helminthiasis of fowls, RAILLIET (*Rec. Med. Vet. Paris*, 8. ser., 7 (1900), No. 2, pp. 36-43).—The author studied an outbreak of helminthiasis among fowls which was caused by *Heterakis perspicillum*, *H. visicularis*, *Darainea cesticillus*, and *D. proglottina*. A serious mortality resulted from the presence of these parasitic worms. The remedies which were tried included calomel, areca nut, santonin, ether extract of male fern, and a mixture of the last two.

Calomel in doses of 2 to 4 cg. gave no result. Areca nut in doses varying from 2 to 6 gm. was ineffective. Santonin, even in doses of 28 mg., produced no appreciable effect. One pullet in a period of 3 weeks received 70 mg. of santonin and 50 cg. of the ether extract of male fern without any appreciable effect on the intestinal parasites.

Forceps for holding pigs during inoculation, BURY (*Berlin. Tierärztl. Wchnschr.*, 1900, No. 33, p. 388).—A brief description of a form of forceps which proved to be convenient for this purpose.

AGRICULTURAL ENGINEERING.

The use of water in irrigation (*U. S. Dept. Agr., Office of Experiment Stations Bul. 86, pp. 253, pls. 50, figs. 18*).—This is a report of investigations made in 1899 under the supervision of E. Mead, expert in charge of irrigation investigations of this Department, and C. T. Johnston, assistant, in accordance with the act of Congress authorizing irrigation investigations by the Department. The report contains papers discussing the results of the year's investigations by E. Mead; tables for use in measuring water, and diagrams showing use in different localities, by C. T. Johnston; and reports and discussions of irrigation investigations in different localities by special agents W. M. Reed, New Mexico; W. H. Code, Arizona; W. Irving, California; O. V. P. Stout, Nebraska; T. Berry, Colorado; C. T. Johnston, Wyoming; S. Fortier, Montana; R. C. Gemmell and G. L. Swendsen, Utah; and D. W. Ross, Idaho. The bulletin explains the methods in use in the arid States in the distribution and use of water in irrigation and gives a large number of measurements made to determine the duty of water and the losses by seepage and evaporation from canals, and discusses the methods by which the water supply may be more effectively and economically utilized in the production of crops. The results show a very variable, but wasteful, use of water in irrigation under present methods and enormous losses from canals and reservoirs by seepage and evaporation. Three tables given in the bulletin afford a very striking illustration of the extent of these losses. These tables show the amount of water (1) flowing into large canals at their headgates, (2) taken out by small canals and laterals, and (3) actually reaching the fields. The difference in results of the 3 measurements shows the approximate loss of water in transit. The following table gives the averages of the 3 classes of measurements:

Measurements at different places in an irrigation system, showing losses in transit.

	Depth.
Measured at the head of large canals	feet... 5.63
Measured at the heads of small canals and laterals.....	do... 2.40
Measured at the margins of fields where used	do... 1.29

"A comparison of the duties secured under many of the canals where measurements were made last year leads to the belief that it will be possible through improved methods to double the average duty now obtained, so that the quantity now required for one acre will serve to irrigate two. If this can be accomplished it will relieve the scarcity under many canals, put an end to many controversies growing out of such scarcity, lessen the expense per acre for water, and immensely increase the productive and taxable resources of the arid States."

Irrigation in New Jersey, E. B. VOORHEES (*U. S. Dept. Agr., Office of Experiment Stations Bul. 87, pp. 40, figs. 5*).—This bulletin discusses the need of irrigation in New Jersey and other States with similar rainfall conditions; reports the results of experiments at the

station and elsewhere in New Jersey during 1899 to determine whether supplemental irrigation is profitable under such conditions; and gives descriptions and statements of cost of a number of small irrigation plants in New Jersey. In the experiments at the station the increase in yield of small fruits due to irrigation was as follows: Blackberries, 1,038 qts. per acre, worth \$93.42; raspberries, 329 qts. per acre, worth \$32.90; and currants, 311 qts. per acre, worth \$31.10. The results of similar experiments in other parts of the State with a variety of crops confirm those obtained at the station.

"So far as rainfall conditions are concerned, New Jersey belongs to the so-called humid region, and may be considered typical of the whole eastern half of the United States. Judging from the results reported in this bulletin, there seems to be no doubt that irrigation for fruits and market gardens, even in regions where rainfall is normally abundant, is a profitable undertaking."

Storage of water on Gila River, J. B. LIPPINCOTT (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 33, pp. 98, pls. 33*).—This is a report on investigations undertaken in 1896 and 1899 with a view to finding means of affording relief to the Pima, Papago, and Maricopa Indians of the Gila River Reservation, who have been deprived of an adequate supply of water for irrigation by diversion of the supply at points in the Gila River watershed above the reservation. The report gives some account of these Indians and of their use of water for irrigation purposes; reviews the causes of the shortage of water and the steps taken to correct it; discusses the water supply of the Gila River basin—precipitation, flow of streams, evaporation, etc.; and records the results of investigation of storage reservoir sites at the Buttes, the Dikes, Riverside, San Carlos, Guthrie, and on Queen Creek, with remarks on irrigable land under the various proposed reservoirs, the distribution of canals, and the organization of irrigation districts. The bulletin also contains a paper by E. Duryee recording the results of investigations on cement, undertaken "(1) to ascertain whether by unusually fine grinding of the cement its strength can be appreciably enhanced and the quantity correspondingly reduced; (2) whether it is feasible to use the rocks found at the dam sites for making a sand cement; (3) whether Portland cement can be economically made at these sites;" the object being to lessen the cost of Portland cement in constructing the dams.

As a result of the investigations the author advises the construction of the San Carlos dam and makes various recommendations regarding further investigations and the management of the stored water and the lands to be irrigated.

The conclusions of the author have been verified by J. D. Schuyler, whose general conclusions and recommendations are incorporated in the report.

Geology and water resources of a portion of southeastern South Dakota, J. E. TODD (*Water Supply and Irrigation Papers, U. S. Geol. Survey, No. 34, pp. 34, pls. 5, maps 5*).—This paper gives the results of investigations of the geology, surface waters, and underground waters of the region named.

Operations at river stations, 1899 (*Water Supply and Irrigation Papers, U. S. Geol. Survey, Nos. 35-39, pp. 471*).—These bulletins give "descriptions of the river stations maintained during 1899 by the United States Geological Survey, together with tables of the average daily height of water, results of measurements of discharge, and rating tables constructed from the latter and applicable in general for the calendar year." For reports of similar data for 1898, see E. S. R., 11, p. 1094.

Pennsylvania road statistics, J. HAMILTON (*Pennsylvania Dept. Agr. Bul. 66, pp. 97*).—This bulletin gives the text of the road law passed by the State legislature in 1897, and tabular statements of the mileage of roads in each township, together with the tax levy, proximity of stone suitable for ballast, and other data.

STATISTICS—MISCELLANEOUS.

Thirteenth Annual Report of Kansas Station, 1900 (*Kansas Sta. Rpt. 1900, pp. XXIV-163*).—The report proper contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1900, a general review of the work of the different departments, and a subject list of station publications issued since the organization of the station. Reprints of bulletins 90-98 of the station on the following subjects are appended: Alfalfa in eastern Kansas (E. S. R., 11, p. 1037), swine plague (E. S. R., 12, p. 190), soy beans—a new drought-resisting crop (E. S. R., 12, p. 142), Kafir corn (E. S. R., 12, p. 332), sugar beets, 1899 (E. S. R., 12, p. 334), station publications (E. S. R., 12, p. 399), fattening hogs with drought-resisting crops (E. S. R., 12, p. 375), soil inoculation for soy beans (E. S. R., 12, p. 333), skim milk calves (E. S. R., 12, p. 472), and scale insects upon Kansas grasses (E. S. R., 12, p. 466).

Thirteenth Annual Report of Maryland Station, 1900 (*Maryland Sta. Rpt. 1900, pp. X+161*).—The report proper contains the organization list of the station, a brief review of the work and publications of the station, a meteorological summary for 1899, and a financial statement for the fiscal year ended June 30, 1900. Bulletins 63-67 of the station on the following subjects are reprinted: Experiments in feeding pigs for the production of pork (E. S. R., 12, p. 174); a study of the cause of mottled butter (E. S. R., 12, p. 182); some important insecticides, fungicides, and apparatus for their application (E. S. R., 12, pp. 572, 581); the occurrence and composition of lime in Maryland, together with a report of the results of experiments in testing its use in agriculture (E. S. R., 12, p. 624); and the culture and handling of tobacco in Maryland (E. S. R., 12, p. 637).

Thirteenth Annual Report of Mississippi Station, 1900 (*Mississippi Sta. Rpt. 1900, pp. 42*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1900, a general report on station work during the year by the director, and more detailed reports by the heads of departments, parts of which are noted elsewhere. Reprints of Bulletins 60 and 62-64 of the station dealing with the following subjects are appended: Value of cotton seed to the farmer (E. S. R., 11, p. 1069); feeding cotton seed, cotton-seed meal, and corn to dairy cows (E. S. R., 11, pp. 1079, 1080); feeding cotton seed, cotton-seed meal, and corn to beef steers (E. S. R., 11, pp. 1022, 1068); cost of wintering the beef herd (E. S. R., 11, p. 1084); feeding cotton seed to hogs (E. S. R., 11, p. 1072); varieties of cotton (E. S. R., 12, p. 844); inoculation of soils (E. S. R., 12, p. 843); and inspection and analyses of fertilizers (E. S. R., 12, p. 841).

Sixth Annual Report of Montana Station, 1899 (*Montana Sta. Bul. 24, pp. 115-152*).—This includes the organization list of the station, a financial statement for

the fiscal year ended June 30, 1899, a report of the director on the work and publications of the station during the year, and departmental reports, two of which are noted elsewhere.

Experiment Station Work—XVI (*U. S. Dept. Agr. Farmers' Bul. 122, pp. 32, figs. 5*).—This number contains articles on the following subjects: Liming grass lands early plowing for wheat, grafting grape cuttings, culture and uses of olives, nuts as food, coffee substitutes, the working of a pure-food law, selling eggs by weight, relation of feed to the flavor of eggs, feeding moldy corn, and preparation of unfermented grape juice.

Press Bulletins Nos. 35 to 70 (*Kansas Sta. Bul. 99, pp. 56*).—This contains reprints of weekly press bulletins issued by the station from April 5, 1899, to June 26, 1900. The articles are based largely on the results of experiments at the station. Following are the subjects treated: Dysentery in calves and other young animals; experiments with swine plague or hog cholera; Kafir corn, alfalfa hay, and soy beans for pork; what is a digestion experiment; skim milk calves; orchard cultivation; a digestion experiment with alfalfa hay; to rid the house of flies, selection of seed wheat; the profitable strawberry bed; early plowing and moisture conservation; soy beans; awnless brome grass; the Kansas Experiment Station; the horn-fly trap experiment; infectious abortion in cattle; alfalfa in eastern Kansas; some nitrogenous forage plants; experiments with sugar beets to 1899 and 1900; Kafir corn; plant breeding by bud selection; digestion experiments with Kafir-corn stover and Kafir-corn meal; protective inoculation against blackleg in cattle; questions about forage plants; how to test the vitality of garden seeds; gophers and crab grass *v.* alfalfa; salsify, or oyster plant; tame grasses for Kansas; *Bromus inermis*; prevention of grain smuts; horn fly remedies; causes of failure in spraying; the cultivated catclasp; the Buffalo tree hopper; the cultivated millets; and botanical notes on wheat and spelt.

The agriculture of the future. Hydraulic agriculture, A. RONNA (*Jour. Agr. Prat.*, 1900, II, No. 51, pp. 897-901; 1901, I, Nos. 1, p. 21; 2, pp. 50-53).—By hydraulic agriculture, as discussed in this article, is meant the use of water not only as a motive power, but also for irrigation and as a carrier of fertilizing material to the soil (warping) in connection with intercultural cover crops which conserve and increase the nitrogen supply of the soil.

Agriculture in Switzerland in the nineteenth century, E. CHUARD (*La Suisse au dix neuvième siècle. Extrait: L'Agriculture. Lausanne: F. Payot; Berne: Schmid & Francke, 1901, pp. 75, figs. 31*).—A historical sketch of Swiss agriculture during the last century with reference to agricultural practices, agricultural societies, schools, and experiment stations, and other agricultural subjects.

Agriculture in the Grand Duchy of Luxemburg, J. J. WAGNER (*Bul. Gesell. Förder. Wiss., Ackerb. u. Künste, Unter-Elsass, 34 (1900), No. 9, pp. 305-312*).—A brief popular article on agricultural conditions in Luxemburg, and discussing in a general way agricultural education and the work of agricultural societies.

Agricultural statistics for New Zealand (*New Zealand Dept. Agr. Rpt. 1900, pp. 347-371*).—Statistics for 1899-1900 on imports and exports. A supplement containing general agricultural statistics is attached.

NOTES.

ALABAMA STATION.—J. G. Gilchrist, of the board of control, died recently at his home in Hope Hull, Ala. His successor has not yet been selected. J. Q. Burton has resigned as assistant chemist to accept a position in the Georgia State Laboratory, and Charles W. Nixon has been appointed in his place.

CALIFORNIA UNIVERSITY AND STATION.—The State legislature has provided an annual appropriation of \$250,000 for the university for the next two years, in addition to its regular income. A department of irrigation has been established in the university, and Elwood Mead, irrigation expert of this Department, has been elected professor of the institutions and practice of irrigation. Professor Mead will deliver a course of lectures at the university, extending over six weeks, on the institutions of irrigation. His new position will not necessitate his relinquishing the charge of the irrigation investigations of the Department, as an assistant professor will be provided.

CONNECTICUT STATE STATION.—Clifford Langley resigned March 1 to accept a position in New York City. He has been succeeded by I. F. Harris.

PURDUE UNIVERSITY AND STATION.—The State legislature has appropriated \$60,000 for a new agricultural building, with \$10,000 a year for two years for maintenance and equipment of the same. Ex-President Benjamin Harrison, who died March 13, was a trustee of the university and station. Within the past twenty-five months President Smart and two of the most prominent trustees of Purdue have died.

IOWA COLLEGE AND STATION.—Homer C. Price, of the University of Ohio, has been elected to the chair of horticulture and forestry in the college and horticulturist of the station. F. R. Marshall has been appointed assistant in animal husbandry, to succeed G. M. Rommel.

KANSAS STATION.—A. S. Hitchcock, botanist of the college and station, has resigned to accept the position of assistant agrostologist in this Department. He entered upon his duties March 1.

NORTH DAKOTA COLLEGE.—The legislature has granted the college one-fifth mill on all taxable property, thus doing away with the necessity for the uncertain biennial appropriation. Plans are being prepared for the completion of the new chemical laboratory and for a science hall, to be built during the present year, and also for a new barn to replace the one recently destroyed by fire.

OHIO STATION.—Clarence W. Waid, B. S., recently assistant horticulturist at the New Hampshire station, has been appointed to the same position at the Ohio station.

SOUTH DAKOTA COLLEGE AND STATION.—The State legislature has provided \$40,000 for an engineering and physics building, and \$10,000 for a building for work in plant breeding. The fund for the general expenses of the college has been increased, and a law passed affirming the Morrill and Hatch funds to the institution in perpetuity. The appropriation of \$1,000 for the experimental work at Highmore was continued. The governor has appointed I. D. Aldrich, of Bigstone, and I. W. Goodner, of Pierre, on the board of regents of education (governing board of the college and station), to succeed H. H. Blair and R. W. Haire.

WYOMING UNIVERSITY.—The legislature has appropriated funds for the completion of the Science Hall and to enlarge the campus. The new building will contain the geological museum and preparatory rooms, the botanical and chemical laboratories, and a large lecture room. A central heating plant for all the buildings will be built.

NECROLOGY.—Dr. George T. Fairchild died March 15, 1901, after a lingering illness, at Columbus, Ohio, where he had gone for medical treatment. According to an account of his life in the Kansas Agricultural College *Industrialist*, Dr. Fairchild was born at Brownhelm, Ohio, October 6, 1838, his father being a farmer and teacher. He was educated at Oberlin College, graduating in the classical course in 1862 and in the department of theology in 1865. He was ordained to the ministry in the Congregational Church, but never served as pastor, as he was elected instructor in the Michigan Agricultural College in 1865 and the next year was made professor of English literature, which position he filled until called to the presidency of the Kansas State Agricultural College in December, 1879. He remained at the head of the latter institution for seventeen and a half years, withdrawing at the close of the collegiate year 1897. Under his presidency this college grew steadily in efficiency and in general appreciation, both in the State and among similar institutions. "The attendance grew from year to year, appropriations by the State legislature became more abundant, and the name of the college became a synonym for thorough educational work. During the first year of his connection with the college the attendance was but 276; during the last year it had grown to 734." Dr. Fairchild was prominently identified with the educational associations of this country. He was a life director in the National Educational Association, and took a prominent part in the Association of American Agricultural Colleges and Experiment Stations, of which he was president in 1897. The last four years of his life were comparatively uneventful. After a period of rest, during which he wrote his book on "Rural Wealth and Welfare," he accepted a call to the chair of English literature at Berea College, Kentucky, which position he occupied at the time of his death.

NATIONAL BUREAU OF STANDARDS.—The recent act of Congress providing for the establishment of this new bureau calls for a director, physicist, chemist, two assistant physicists or chemists, several laboratory assistants, a secretary, engineer, and mechanic. The appointment of Dr. Samuel W. Stratton, of the University of Chicago, as director, has been announced. Dr. Stratton has been in charge of the Office of Standard Weights and Measures in Washington. The appropriation for the bureau carries \$27,140 for salaries, \$100,000 toward the erection of a fire-proof laboratory, the entire cost of which is not to exceed \$250,000, \$25,000 for a site for the laboratory, \$10,000 for equipment, and \$5,000 for general expenses, making a total of \$167,140. A visiting committee of five members, consisting of experts in the various interests involved, but not in the employ of the Government, is provided for. Fees will be charged for the services of the bureau in making comparisons, calibrations, tests of apparatus, or investigations, except those performed for institutions connected with the Federal or State governments. Germany is said to provide \$116,000, Great Britain \$62,100, and Austria \$46,000 annually for the maintenance of similar standardizing bureaus.

AGRICULTURAL EDUCATION IN GERMANY.—According to a note* in the *Gardeners' Chronicle* (29 (1901), No. 734, p. 45), there are at present 241 institutions in Germany giving instruction in agriculture, exclusive of the special schools of horticulture, dairying, and other industries. There are chairs of agriculture and agricultural institutes connected with 12 universities, and in addition 20 schools of agriculture, not including the primary schools, where the education given is of a more elementary character. Traveling teachers also visit remote districts to instruct the peasants and show them the best methods of cultivation, etc.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director.*

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

Editorial notes: Experiment-station farms, and the movement for their establishment in Germany.....	901
Recent work in agricultural science.....	905
Notes.....	998

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

Report of the chemist, G. W. Shaw.....	906, 907
Chemical division, H. J. Wheeler.....	907
On uniformity in soil analyses, A. D. Hall.....	905
The detection of lead in potable water, Bellocq.....	906
Some physical and chemical properties of salad oils, G. E. Colby.....	906

BOTANY.

Agrostological notes, F. Lamson-Scribner and E. D. Merrill.....	911
Inventory of foreign seeds and plants, J. G. Smith.....	911
The university botanic garden, J. B. Davy.....	912
Notes on plants received for identification, J. B. Davy.....	912
Report on the investigations at the climatological station of Juvisy during 1899, C. Flammarion.....	909
Physiological experiments on the germination and growth of plants in rarefied air, F. Schaible.....	909
Notes on the germination and seedlings of certain native plants, S. Coulter...	910

	Page.
Investigations on the formation of proteids by plants in darkness, Marie Maliniak	910
The occurrence of calcium oxalate and lignin during the differentiation of the buds of <i>Prunus americana</i> , H. L. Bolley and L. R. Waldron	910
On the poisonous properties of some alkaline compounds toward higher plants, H. Coupin	911

FERMENTATION—BACTERIOLOGY.

The bacterial air flora of the semidesert region of New Mexico, J. Weinzierl...	913
The influence of the temperature of liquefied air on bacteria, A. Macfadyen and S. Rowland	913
Effect of different degrees of light on the multiplication of water bacteria, F. T. Bioletti	914
Fermentation of galactose, F. Dienert.....	915

METEOROLOGY—CLIMATOLOGY.

West Indian hurricanes, E. B. Garriott	920
The fifth annual report for the year 1899 of the agricultural experiment station of Ploty	916
Work at the station of agricultural climatology of Juvisy during the year 1899, C. Flammarion.....	918
Meteorological observations, A. O. Leuschner and Y. Kuno	921
Meteorological observations, J. E. Ostrander and C. L. Rice	918
Meteorological record for 1899.....	921
Meteorological summary for 1899, C. A. Patton.....	919
Report of the meteorologist, N. Helme.....	919

AIR—WATER—SOILS.

Waters, E. W. Hilgard et al.....	926
Soils, lands, and soil moisture, E. W. Hilgard and R. H. Loughridge	921
Alkali and alkali soils, R. H. Loughridge	923
Preliminary account of the soil survey work in North Carolina, B. W. Kilgore.	924
The Illinois glacial lobe, F. Leverett.....	924
The soil zones of European Russia in connection with the salt content of the subsoils and with the character of the forest vegetation, G. Vissotski.....	925
Acidity of upland soils, H. J. Wheeler and B. L. Hartwell.....	927
Laterites, P. A. Zemyachenski	926

FERTILIZERS.

The manurial value of the excreta of milch cows, W. S. Sweetser.....	927
Denitrification of nitrate of potash under the influence of reducing substances, M. Knovalov	928
Fertilizer experiments with different sources of phosphoric acid, H. J. Patterson.	930

EXPERIMENT STATION RECORD.

VOL. XII.

No. 10.

The question of the establishment of experimental farms in connection with the experiment stations is being agitated to considerable extent in Germany. This plan of carrying on a small farm in connection with the station, where field and feeding experiments are conducted on a more or less practical scale, is referred to as the "American system." Several years ago Professor Maercker, of the Halle Station, made a tour of the American stations, and was much impressed with the value of the farm portion of the station equipment as an accessory means of studying certain problems closely related to practice, and of verifying and testing the practical application of laboratory investigations.

The Lauchstädt Experimental Farm, which is connected with the Halle Station, is an outgrowth of Professor Maercker's American trip, and is the only German representative of the so-called American system. This farm was started about five years ago. In addition to its fields and plats, where experiments in culture, fertilizing, and management of field crops are carried on, it has a herd of cattle which are used for feeding and dairy experiments. Several annual reports of its operations have been reviewed in the Record as they appeared. The farm has evidently attracted a good deal of attention in Germany during the few years it has been in operation, and has appealed strongly not only to practical farmers and agriculturists, but to higher officials as well.

As is generally known, the German stations do not have any considerable area of land or conduct what we understand as field experiments, except as they may do so in cooperation with farmers, their culture work being carried on for the most part in vegetation pots or small plats and quite restricted. The same is true of their feeding experiments, which are made with a small number of animals and usually cover only short periods. While their strictly scientific experiments have taught us much regarding the nutrition of animals and the utilization of food, as well as the methods of investigation, their more practical experiments must be regarded as quite inferior in point of method to their research work.

The Lauchstädt Experimental Farm was in a sense a new departure in experiment station work in Germany. Although it has been in

operation so short a time, it has given rise to a popular demand for a number of stations on that plan, which appears to be receiving considerable support from specialists and the press. Last fall Professor von Rümker, of Breslau, published an article in the *Journal für Landwirtschaft*, on the importance of experimental farms in connection with agricultural experiment stations. In this he paid a high tribute to the American stations, and maintained that their German representative at Lauchstädt had abundantly justified its establishment. He thought it should serve as an example to many other German stations, and believed that the establishment of modern experimental farms was a natural demand of the times which promised to mark an epoch in the history of the German experiment stations. He earnestly advocated relieving experiment stations of control work for the most part, and the establishment of experimental farms in connection with a considerable number of stations. He held these farms to be of great advantage to agricultural production, and a potent means for the improvement of agricultural practice.

This suggestion of Professor von Rümker's has not met with universal approval. In a reply to his article, in a late number of *Die landwirtschaftlichen Versuchs-Stationen*, Prof. J. König, the eminent director of the experiment station at Münster, in Westphalia, takes very decided exception to von Rümker's opinion of the value or applicability of the results obtained at such experimental farms. He shows from a review of the history of the German stations that when they were first established they were expected to work out formulas and practical directions for feeding and manuring, and that, accordingly, many of the stations were given considerable tracts of land or had such land under their control. It was found more advantageous for the research, however, to move the stations to towns or cities where educational institutions were located; and he contends that the wisdom of this course has been fully demonstrated, and that the results accomplished do not warrant recommending a return to the old order of things. The experimental farm, he says, furnishes only a mass of experiences from which generalizations can not be made or the true significance measured; and he holds that such experimenting is not scientific and does not furnish practical indications which are of more than local and temporary application. The attempt of the stations to meet the early requirements and prescribe rules for agricultural practice has not been successful for the reason that conditions vary so greatly in different localities and at different times. He even holds that experimental fields are dangerous for such farmers as are inclined to follow results blindly without considering carefully their own conditions. The thing which the German stations stand in most need of, he says, is not a change in their system of operations, but more free time for research. In conclusion, he states as his judgment that experimental farms on the plan of that at Lauchstädt are useful for purposes of instruction at agricultural high schools, but are not necessary for experiment stations, because we lack as yet the necessary

basis for interpreting the results, and this basis can not be worked out in experiments on a large scale where a variety of unknown conditions prevail.

This discussion is interesting to those connected with the stations in this country, where similar experience has been passed through. The earlier stations were patterned very largely after the German stations. Later it was found to be desirable for a number of reasons to have fields and herds connected with the stations. The tendency at first was to go rather to the extreme in this matter, but as experience has been gained and the confidence of the farmers secured, there has been a marked tendency to diminish the areas under cultivation, to give far less prominence to the commercial features of farming, and to combine, as far as practicable, with the farm operated by the agricultural college. Visitors to our stations do not always realize that the farm which they see is not operated entirely by the station, and that the larger portion of it is frequently carried on by the college for use in connection with its instruction, a partnership which in many cases has been mutually helpful.

The Lauchstädt farm is hardly a fair representative of the American station farm as it is carried on to-day, and as many of its experiments have been very practical and very unlike the ordinary work of most of the German stations, it is not surprising that a proposition to increase the number of such farms should meet with considerable disapproval. Our experience, however, has indicated that without maintaining a large and expensive farm, where many of the operations are purely practical, commercial, or merely for demonstration, comparatively small farms conducted on the experimental basis may be made very useful to the stations in their work, and to the farmers in whose interest the work is carried on. As primary means of investigation the experiment station farms have often been overrated. Their greatest usefulness is as secondary, or intermediate, agencies for the reduction of theoretical results of scientific investigation to a practical basis. It is believed that such experimental farms would prove to the advantage of the German stations in much the same way that they have to the stations in this country, especially if they are to give serious attention to improving agricultural practice.

It seems entirely reasonable that the feasibility and the practical application of results of investigations made on a small scale in laboratories, plant houses, experimental stables, or even on field plats, should be determined first by the stations making such investigations. Otherwise the results must be looked upon as largely theoretical, and if made use of at all by farmers are likely to be misleading. As a rule such studies conducted on a farm basis show that many factors not considered in the smaller trials have to be taken into account in actual practice. The latter studies oftentimes call for the exercise of as much scientific acumen and knowledge and more inventive and prac-

tical skill than the laboratory investigations. Take the case of some of the investigations which have been made on the laboratory scale in the preservation of barnyard manure. From the results obtained on a small scale, methods of treatment have been indicated which have not always been found advantageous when put to the test on a large scale, on account of other factors which entered in. Again, the plan of inoculating the soil with micro-organisms for legumes, either with pure cultures or with soil containing these germs, seemed quite simple in theory, but in practice numerous difficulties were encountered which it has required skill and perseverance to overcome. Studies of the availability of fertilizing materials, and the combating of insect pests and plant diseases present similar analogies. The laboratory research frequently does not end the investigation of a subject if any regard is had to its introduction into practice, and without this the result of the investigation is merely a contribution to science and in the case of station work does not accomplish its full purpose.

The American stations have profited greatly by the investigations and researches of the German stations, and to a certain extent have emulated their example. Their greatest success, however, has not been in the field of pure science, but in improving the conditions and practices of the various branches of agriculture; and in doing this they have taken advantage of the agricultural investigations of the world as well as of their own research work and experiments.

Professor König minimizes the importance of this, and is not inclined to give the American stations credit for having conducted any investigations of real value. For he intimates, in reply to von Rünker's praise of the American system of stations, that "magnificently equipped buildings, beautiful photographic reproductions, a large amount of labor, and long series of analyses without deductions" do not mean scientific contributions, and he adds that he knows of no results of American investigations which have or should have influenced the direction of their investigations. Be this as it may, there can be little doubt that through the course which the American stations have pursued they have exerted a greater influence on American agriculture during the time they have been in operation than the German stations have upon the agriculture of that country in the same time, in spite of the far larger number of well-trained and highly educated agriculturists and farm managers in the older country. It is quite certain that if the American stations had confined their operations to laboratories, greenhouses, and small plats, and had conducted their feeding experiments with two or three animals at a time or with the respiration apparatus exclusively, their progress in reaching and benefiting the American farmer would have been exceedingly slow, and they would not have won his confidence to the extent of becoming by common consent his advisers in nearly every branch of farming operations.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

On uniformity in soil analyses, A. D. HALL (*Analyst*, 25 (1900), No. 296, pp. 281-291).—This article gives the recommendations of a committee of the Agricultural Educational Association, consisting of T. S. Dymond, M. J. R. Dunstan, C. M. Luxmoore, T. B. Wood, and A. D. Hall, as well as some of the results obtained by members of the committee in testing the methods proposed and a discussion of them by B. Dyer and others. The recommendations are as follows:

“(1) *Taking sample*.—Under ordinary conditions the sample shall be taken to a depth of 9 in., but in case of shallow soils to such lesser depth as marks a natural line of demarcation. The committee approves of the use of the auger as one method that may be adopted for taking samples. Several cores should be taken and mixed for analysis.

“(2) *Drying*.—The sample shall be air-dried for analysis. The drying may be accelerated by heating to a temperature not exceeding 40° C., but in all cases the soil should be finally left for a day or two, spread in a thin layer, and exposed to the air at the ordinary temperature of the room.

“(3) *Sifting*.—A sieve with round holes, 3 mm. in diameter, shall be used to separate the fine earth for analysis from the stones and gravel. Gentle pressure with a wooden or caoutchouc pestle or other means may be adopted to break up aggregates of clay and silt, but care should be taken not to crush any of the stones or lumps of chalk.

“For determination of the ‘available constituents’ the ‘fine earth’ is used without grinding. For the other determinations 100 gm. or more of ‘fine earth’ is sifted through a woven sieve of 40 meshes to the inch, or a sieve with round holes of 1 mm. in diameter. What is retained by the sieve is ground till it will pass through, and the whole mixed. Perforated zinc, with holes $\frac{1}{8}$ in. and $\frac{1}{32}$ in. diameter, is commercially obtainable, and forms a convenient material for the construction of the two sieves. . . .

“(4) *Determination of moisture*.—The sample is dried in the steam oven to constant weight.

“(5) *Determination of loss on ignition*.—The result shall be so expressed as not to include the carbon dioxid expelled from the carbonates nor the moisture previously determined.

“(6) *Determination of nitrogen*.—Unless otherwise specified, the nitrogen shall be determined by Kjeldahl’s method.

“(7) *Determination of carbonate of lime*.—The carbon dioxid evolved on treatment of the fine earth with acid is calculated as carbonate of lime.

“This is regarded as a convenient measure of the ‘available basicity’ of the soil, without discriminating between carbonates of lime and magnesia.

“(8) *Determination of ‘total’ mineral constituents*.—The fine earth is boiled with strong hydrochloric acid in an open flask for a short time in order that the acid may

attain constant strength, and digested at the ordinary water bath or steam oven temperature for 40 to 48 hours, the flask being loosely stoppered. In this solution the phosphoric acid and potash are determined, and other mineral constituents as desired. . . .

“(9) *Determination of available phosphoric acid and potash.*—Unless otherwise specified, the method described by Dr. B. Dyer (*Jour. Chem. Soc.*, 1894, *Trans.*, p. 115) shall be followed, the quantities used being 200 gm. unground fine earth and 20 gm. citric acid in 2,000 cc. water, no further addition of citric acid being made.

“(10) *Expression of results.*—Unless otherwise stated, results shall be expressed as percentages calculated on the fine earth in an air-dry state.”

As will be seen, the recommendations deal only with those determinations with regard to which there is a general consensus of opinion and do not enter into the questions of interpretation of results nor the details of analytical processes and manipulation.

The detection of lead in potable water, BELLOCQ (*Jour. Pharm. et Chim.*, 6. ser., 13 (1901), No. 2, pp. 56, 57).—For this purpose the author makes use of a modification of a reagent described in an earlier article,¹ which contains pure zinc sulphate ($\frac{1}{3}$ saturated solution) 30 cc., soda solution 30 cc., sodium carbonate (saturated solution) 40 cc., the modification consisting of the substitution of ammonia for the soda solution. From 5 to 10 cc. of this reagent is added to 1 to 2 liters of the water and after standing a few hours the supernatant liquid is decanted and the precipitate collected on a filter, dried, carefully detached from the filter, dissolved in warm acetic acid, filtered, and the filtrate tested with potassium chromate for lead.

Some physical and chemical properties of salad oils, G. E. COLBY (*California Sta. Rpt.* 1898, pp. 165–169).—The author has compiled data relative to the index of refraction, specific gravity, thermal degree, viscosity of soap solutions formed from oils, iodine number, saponification value, melting point of fatty acids from oils, and special tests of American and European salad oils. The data relative to the thermal degree and viscosity of soap solutions formed from pure olive oils and a number of other oils are tabulated. The results are summarized and the value of the different determinations for the detection of adulterants is discussed.

“Pure olive oil of California production, according to the data at hand, has an index of refraction at 15.5° C. of 1.4689 to 1.4717, a specific gravity at 15.5° C. of from 0.9140 to 0.9185, a thermal degree of from 34 to 47° C., a high viscosity of soap solution formed from the oil, an iodine number varying from 77.7 to 93.5, a saponification value of about 190, and a melting point of fatty acids from the oil from 21 to 26° C.”

Report of the chemist, G. W. SHAW (*Oregon Sta. Rpt.* 1898, pp. 38–55).—An outline is given of the work of the department during the year and some of the results of investigations reported in earlier publications of the station are summarized. A table shows the character and acidity of 34 samples of soil from different localities in the State. Of the samples examined 60 per cent were acid. Analyses are given of 17 samples of prunes, 4 of strawberries, 2 of rhubarb, 13 of limestone, 3 of gypsum, 8

¹*Jour. Pharm. et Chim.*, 6. ser., 12 (1900), No. 3, p. 103.

of Paris green, and 14 of water. Notes are given on the results of an examination of headcheese considered as causing several cases of illness.

Report of the chemist, G. W. SHAW (*Oregon Sta. Rpt. 1899, pp. 20-27*).—Analyses are given of a number of samples of leachings from alkali soils. The alkali was generally of the black kind and was concentrated in the first 6 in. of the soil. Analyses are also given of 7 samples of gypsum, 4 of limestone, 3 of Paris green, 3 of soil, and 1 each of mixed hay, barley, salsify, laurel green, and crematory ashes.

Chemical division, H. J. WHEELER (*Rhode Island Sta. Rpt. 1900, pp. 279-292*).—A report of the work of the year in the chemical division in the following lines: Fertilizer and feeding stuffs inspection, methods of analysis, special chemical investigations, pot experiments, improvement of laboratory facilities, correspondence and publications, and miscellaneous analytical work. Under the last head are reported analyses of muck, air-slaked lime, ashes, calcium carbide waste, salt, sodium carbonate, muriate of potash, potassium carbonate, sulphate of potash, potassium nitrate, acid phosphate, dissolved boneblack, floats, tankage, fine-ground bone, nitrate of soda, sulphate of ammonia, dried blood, wool waste, rice meal, wheat bran, cotton-seed meal, corn meal, oats, cracked corn, linseed meal, boiled blood and bone, and three poultry feed mixtures (with narrow, medium, and wide nutritive ratios).

Detection of the adulteration of bone superphosphate, H. LASNE (*Rev. Phys. Chim.*, 4 (1900), p. 397; *abs. in Chem. Ztg.*, 24 (1900), Nos. 28, *Repert.*, p. 99; 78, *Repert.*, p. 282).—This is a description of the analytical methods employed by the author which have already been noted (*E. S. R.*, 11, p. 104).

The theory and practice of the analysis of drinking waters, G. KÄRRHEL (*Theorie und Praxis der Trinkwasserbeurteilung. Munich: Oldenbourg, 1900, pp. VII+234*).

Permanent standards for use in the analysis of water, D. D. JACKSON (*Tech. Quart.*, 13 (1900), No. 4, pp. 314-326, *figs. 4*).—This article describes the permanent standards already in use for the determination of color, turbidity, and nitrates, and discusses new standards proposed for the determination of ammonia, nitrite, and iron. For the determination of free and albuminoid ammonia and iron the author proposes the use of platinum-cobalt solutions; for nitrites, cobalt-copper solutions.

Preliminary experiments on the determination in cultivated soil of assimilable phosphoric acid, A. DE SIGMOND (*Ann. Sci. Agron.*, 1900, II, No. 3, pp. 451-463).—In these experiments a comparison was made between the indications furnished by Schloessing's method of digesting in dilute nitric acid (*E. S. R.*, 11, p. 131) and the results of pot experiments with phosphates on different soils. As a rule the soils showing a considerable percentage of phosphoric acid soluble in dilute nitric acid (in general 0.075 per cent) were not benefited by phosphatic fertilizers, although it was not always true that soils containing less than 0.075 per cent of phosphoric acid soluble in the nitric acid were in need of such fertilizers.

A simple and quick method for determining humus acid, H. BORNRÄGER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 12, pp. 790, 791).—The method proposed is in general a modification of Messon's method for the examination of cochineal.¹

On the analysis of peat, H. BORNRÄGER (*Ztschr. Analyt. Chem.*, 39 (1900), No. 11, pp. 694-698).—Brief directions are given for the determination of water, waxy substances, nitrogen, humus acids, and ash.

Determination of starch in potatoes, G. BAUMERT and H. BODE (*Ztschr. Angew. Chem.*, 1900, pp. 1074, 1111; *abs. in Analyst*, 26 (1901), No. 298, p. 20).—In the method proposed the cellulose is first removed by digestion in an autoclave and filtering. The starch is then separated from nitrogenous and other substances by precipitation with alcohol in alkaline solution, dried and weighed. The loss of weight on ignition gives the amount of starch.

¹ *Farben Ztg.*, 1900, p. 238.

Methods for the examination of milk, P. SOMMERFELD, translated by A. T. PETERS and R. S. HILTNER (*Chicago: A. Eger, 1901, pp. 96, figs. 7*).—This little volume is designed for the use of commercial analysts, inspectors, and health officers. It describes methods for the complete analysis of milk, detection of preservatives, detection of adulteration, estimation of insoluble foreign substances, examination of condensed milk, and the bacteriological examination of milk. The translators have followed closely the German edition, which undoubtedly accounts for the presence of some methods which are no longer employed in this country and the omission of others which are in common use. In other words, the book has been translated literally rather than adapted to American readers, although fortunately several footnotes, including one describing the Babcock test, have been added by the translators. An appendix contains a short bibliography.

The estimation of milk sugar in milk by polarization and by reduction, A. SCHEIBE (*Ztschr. Analyt. Chem., 40 (1901), No. 1, pp. 1-14*).—In a comparison of the two methods the author found average higher results by polarization. In order to correct this he proposes multiplying the results obtained by polarization by the following factors: For whole milk, fat content 2.8 to 4.7 per cent, 0.94; skim milk, 0.97. No factor is recommended for cream or colostrum.

The testing of milk for carbonate and bicarbonate of soda, P. SÜSS (*Pharm. Centralhalle, 1900, No. 41, pp. 465, 466; abs. in Ztschr. Untersuch. Nahr. u. Genussm., 4 (1901), No. 2, p. 78*).—By adding 5 to 10 cc. of a 0.2 per cent alcoholic solution of alizarin to 100 cc. of milk a rose color will be produced in the presence of 0.05 to 0.1 per cent of carbonates of soda. In their absence only a light yellow color will result.

A new process for detecting sesame oil in vegetable and animal oils, TAMBON (*Jour. Pharm. et Chim., 6. ser., 13 (1901), No. 2, pp. 57, 58*).

Simple tests of the action of zymase, R. ALBERT (*Ber. Deut. Chem. Gesell., 33 (1901), No. 19, pp. 3775-3778*).

On the question of the inversion of cane sugar, E. O. VON LIPPMANN (*Ber. Deut. Chem. Gesell., 33 (1901), No. 19, pp. 3560-3564*).

Analyses of fruit essences, G. FABRIS (*Ann. Lab. Chim. Cent. Gabelle, 4 (1900), pp. 41-141; abs. in Jour. Chem. Soc. [London], 80 (1901), No. 458, II, p. 49*).

An improved method for the preservation of normal sodium hydrate, E. DOWZARD (*Chem. News, 83 (1901), No. 2146, pp. 18, 19, fig. 1*).—The solution is covered in the bottle with a layer of white mineral oil (B. P. 1898) $\frac{1}{4}$ in. thick. The bottle is connected with a filter pump by which any excess of solution which may have been siphoned off may be sucked back into the bottle.

The evolution of the thermometer, H. C. BOLTON (*Easton, Pennsylvania: The Chemical Publishing Co., 1900, pp. 98, figs. 6*).—This little book traces the history of the development of the thermometer from the time of Galileo's invention of his open-air thermometer to the present date. A list of authorities consulted is given.

An automatic temperature regulator, C. T. KNIPP (*Phys. Rev., 12 (1901), No. 1, pp. 47-49, figs. 3*).—This is an electric device for regulating the temperature of an electric heating apparatus.

A simple thermoregulator, A. VON KALECSINSZKY (*Ztschr. Analyt. Chem., 39 (1900), No. 11, pp. 698, 699*).

An apparatus for the generation of dry hydrochloric-acid gas, A. GWIGGNER (*Ztschr. Angew. Chem., 1900, No. 52, p. 1308, fig. 1*).

New laboratory apparatus, W. BERSCH (*Ztschr. Landw. Versuchs. Oesterr., 4 (1901), No. 1, pp. 4, figs. 3*).—An extraction apparatus with a special form of aluminum capsule and an apparatus for drying in different gases are described.

New laboratory apparatus, P. METZGER (*Ztschr. Analyt. Chem., 39 (1900), No. 12, pp. 791-794, figs. 3*).—A titration apparatus and devices for sampling solid and liquid substances are described.

BOTANY.

Report on the investigations at the climatological station of Juvisy during 1899, C. FLAMMARION (*Bul. Min. Agr. [France]*, 19 (1900), No. 5, pp. 860-864).—In continuation of the investigations previously reported (E. S. R., 11, p. 907) the author reports upon the effect of different colored light on the development of plants, the persistence of the leaves of young oak trees when subjected to blue light, and the action of different parts of the solar spectrum on the coloration of plants. The experiments in radioculture, in which the effect of the different solar radiations in the development of the plants was investigated, gave results similar to those previously reported. The author found that there was no difference due to species or varieties, age of the plant, or whether shrubby or herbaceous. The maximum growth always took place in the red spectrum.

The experiments continued with the young oak trees in the blue light showed that their leaves were retained when subjected to this radiation. The action seems to be explained by the statement that the blue light prevents the transformation and transportation of the elaborated material which determines the fall of the leaves. It was found to have exercised some very marked influences upon the chlorophyll of the leaves.

The effect of the different radiations of the spectrum on the coloration of plants was further investigated with the result that the different portions of the solar spectrum influenced the coloration of the foliage and flowers of a number of species. The author states that the action of light on plant tissues is without doubt of a chemical nature, and in influencing coloration the light seems to liberate certain substances which react upon the chromoleucites.

Physiological experiments on the germination and growth of plants in rarefied air, F. SCHAIBLE (*Beitr. Wiss. Bot.*, 4 (1900), pp. 93-148, pls. 8, figs. 3; *abs. in Bot. Centbl.*, 82 (1900), No. 2, pp. 52-54).—The previous investigations on the effect of diminished atmospheric pressure on the germination and growth of plants are reviewed, and an account given of experiments with *Phaseolus vulgaris*, *Lepidium sativum*, *Satureia hortensis*, *Vicia faba*, and *Hortensia vulgare*, in which separate lots of seeds and plants were subjected to three different atmospheric pressures for a considerable period of time. A special form of apparatus was devised whereby the atmosphere could be changed without affecting the pressures, which were kept constantly at 570 to 580 mm., 170 to 180 mm., and 180 to 190 mm. As previously, it was found that under diminished atmospheric pressure the growth of plants was more vigorous than under normal barometric pressures, but that germination was slower and fewer seeds sprouted

than under normal conditions. The phenomena exhibited were the same as those shown by plants grown in atmospheres containing a diminished content of oxygen.

Notes on the germination and seedlings of certain native plants, S. COULTER (*Proc. Indiana Acad. Sci.*, 1898, pp. 215-222).—In order to account for the distribution of certain species of plants, the author made a study of the effects of temperature and moisture changes upon the seedlings of a large number of common plants. Many of the plants experimented with produced large numbers of viable seeds, but the plants themselves do not seem to be becoming much more abundant. This applies particularly to the Compositæ, and the results of the experiments showed that among the Compositæ the percentage of germination is comparatively low. This is apparently due to an extreme sensitiveness on the part of the embryo to external conditions, to which should probably be added imperfect pollination. The seedlings of many plants are found to be extremely sensitive to temperature and moisture changes, either in the soil or atmosphere. These factors prove effectual in limiting the distribution of many plants.

Investigations on the formation of proteids by plants in darkness, MARIE MALINIAK (*Rev. Gén. Bot.*, 12 (1900), No. 141, pp. 337-343).—The literature bearing upon this subject is briefly reviewed and the conflicting statements pointed out, after which the author gives the detailed results of her own experiments with maize and *Vicia faba*.

The experiments with maize were made by germinating the seed in sand in darkness, and after 8 or 10 days transferring to cultures containing saccharose and glucose. To some of the cultures asparagin and urea were added. The cultures were maintained for a number of days, the solutions being changed daily to prevent attacks of bacteria. At the expiration of the period, the plants were dried and the nitrogen determined by the Kjeldahl method, the albuminoids being determined by Stutzer's method. The experiments with maize demonstrated that in the presence of glucose and saccharose, together with asparagin, the plants were able to form albuminoid materials in darkness.

The experiments with *V. faba* were conducted in a similar manner with similar results.

The occurrence of calcium oxalate and lignin during the differentiation of the buds of *Prunus americana*, H. L. BOLLEY and L. R. WALDRON (*Proc. Amer. Assoc. Adv. Sci.*, 48 (1899), p. 304).—The authors note the occurrence of crystals of calcium oxalate and the presence of lignified tissues, as observed in the study conducted upon the development of the buds of *Prunus americana*. It was found that the crystals of calcium oxalate occurred in very great abundance in the meristematic tissues of the bud, and in the very youngest stages

of the bud scales. As the tissues develop, the amount of calcium is lessened proportionately. While it is usually assumed that calcium oxalate is a waste product of metabolism, its occurrence in such large quantities would seem to indicate that it might have some definite value at this particular time in the life history of the plant.

On the poisonous properties of some alkaline compounds toward higher plants, H. COUPIN (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 12, pp. 791-793).—The author reports a series of experiments in which the poisonous effects of bromid, chlorid, iodid, nitrate, chlorate, acetate, and phosphate of calcium, strontium, and barium are shown by the action of their solutions upon the growth of wheat.

The compounds of calcium affected the plants unequally, the bromid, phosphate, and nitrate being but very slightly injurious, the iodid strongly, with the acetate and chlorid intermediate. The nitrate of strontium is but slightly poisonous, the bromid and chlorid somewhat more, while the iodid was extremely injurious. All of the compounds of barium were more or less injurious, the bromid being the least and the chlorate most poisonous, with the others intermediate, except the iodid, which was about as injurious as the chlorate. In general the poisonous properties of calcium, strontium, and barium increase with their atomic weights.

How crops grow; a treatise on the chemical composition, structure, and life of the plant, S. W. JOHNSON (*New York: Orange Judd Co., 1900, rev. ed., pp. VI + 416, figs. 69*).

Annual report of the consulting botanist, W. CARRUTHERS (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. 4, pp. 731-741, figs. 14).—Miscellaneous notes are given on a number of plant diseases, supposed poisonous plants, weeds, grass mixtures, and seed testing. The first appearance of the pear scab (*Fusicladium pyrinum*) in England is noted. Serious injury to beans by *Sclerotinia sclerotiorum* is reported. *Helminthosporium gramineum* reappeared on barley during the year, causing some loss. Notes are given on ergot, corn cockle, and *Lathyrus sativa* as poisonous to stock. A number of weeds are described and means for their destruction suggested. The report concludes with a description of a bacterial disease of turnips noted elsewhere.

Agrostological notes, F. LAMSON-Scribner and E. D. MERRILL (*U. S. Dept. Agr., Division of Agrostology Circ. 27, pp. 10*).—Notes are given on studies made on the grasses of the herbarium of H. Muhlenberg. Two new species of *Eatonia* are described, as well as a new variety of *Panicum nashianum*. Notes are given on the nomenclature of various species and varieties of grasses, together with the publication by C. V. Piper of new names of *Melica bulbosa* and *Stipa occidentalis*. The names suggested for these grasses are *M. bella* and *S. thurberiana*.

Inventory of foreign seeds and plants, J. G. SMITH (*U. S. Dept. Agr., Division of Botany, Inventory No. 7, pp. 86*).—A catalogue of recently introduced seeds and plants is given which includes the collections of the explorers of the Section of Seed and Plant Introduction, as well as a large number of donations from miscellaneous sources. The principal sources through which the seeds and plants were obtained were W. T. Swingle, who collected in France, Algeria, and Asia Minor; M. A. Carlton, in Russia; S. A. Knapp, in Japan; and B. Lathrop and D. G. Fairchild, in South America and the West Indies.

The university botanic garden, J. B. DAVY (*California Sta. Rpt. 1898*, pp. 252-255).—Brief notes are given on the donations to the botanic garden and lists are given of donors and materials received.

Notes on plants received for identification, J. B. DAVY (*California Sta. Rpt. 1898*, pp. 256-261).—Notes are given on a number of plants received from different localities, in which suggestions as to their economic value are added.

The common origin of the tissue of leaves and stems in phanerogams, L. FLOT (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 27, pp. 1319-1322, figs. 3).—A morphological study is given in which the various tissues are traced from the stem, through the buds into the leaves.

The influence of root curvature on the distribution and arrangement of roots, F. NOLL (*Landw. Jahrb.*, 29 (1900), No. 3, pp. 361-426, pls. 3).

Concerning Anthophæin, a brown coloring matter of flowers, M. MÖBIUS (*Ber. Deut. Bot. Gesell.*, 18 (1900), No. 8, pp. 341-347).—An account is given of the separation by the author from the dark brown portions of the flowers of *Vicia faba* of a coloring matter, to which the name Anthophæin is given. A similar substance is found present in many brown flowers.

The presence of dextrose and levulose in the leaves of the sugar beet, L. LINDET (*Sucr. Indig. et Coloniale*, 55 (1900), No. 17, pp. 523-529).

A new glucosid occurring in the seed of Erysimum, SCHLAGDENHAUFFEN and REEB (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 19, pp. 753-755).—The authors have separated from a number of species of *Erysimum* a new glucosid, to which the erysimin is given. Its chemical and physiological action are indicated.

Concerning the effect of hydrochloric acid upon the assimilation of plants, C. WIELER and A. HARTLEB (*Ber. Deut. Bot. Gesell.*, 18 (1900), No. 8, pp. 348-358).—As a result of investigations upon a number of plants, the author found that an atmosphere containing 1 part hydrochloric acid to 500,000 reduced the power of assimilation from 50 to 60 per cent.

Digestion in the leaves of nepenthes, G. CLAUTRIAU (*Extract Mem. Acad. Roy. Belg.*, 59 (1900), pp. 55).

Concerning the cause, size, number, distribution, and function of tubercles on the roots of leguminous plants, L. HILTNER (*Arb. K. Gesundheitsamte, Biol. Abt.*, 1 (1900), No. 2, pp. 177-222, pl. 1).—A critical review is given of the literature relating to this subject, in which the present status of the knowledge regarding root tubercles and their function is summarized.

The morphology and physiology of Mycoderma cucumerina, B. HEINZE (*Landw. Jahrb.*, 29 (1900), No. 3, pp. 427-466, pls. 3).—Studies are given on the morphology and physiology of this common mold, which occurs as a gray or grayish white mass upon solutions containing sugar or alcohol.

The growth and abnormal formation of conidia of Dematium pullulans, A. KLÖCKER and H. SCHÖNNING (*Compt. Rend. Travaux Lab. Carlsberg*, 5 (1900), No. 1, pp. 47-57, figs. 6).—It was found that *Dematium pullulans* and other species of fungi, under similar conditions of growth, form their conidia in the interior of certain cells. The conditions causing this abnormal formation are lack of nutrition and too abundant humidity.

The capacity of fungi to absorb humin substances, F. REINITZER (*Bot. Ztg.*, 1. Abt., 58 (1900), No. 4, pp. 59-73; *abs. in Jour. Roy. Micros. Soc.* [London], 1900, No. 6, p. 702).—The author limits the term humus to those substances which are compounds of humin and confirms Hoppe-Seyler's statement as to their extreme power to withstand decomposition under ordinary circumstances. This, however, according to the author, applies only to the power of living organisms to extract carbon from the humus. If another source of carbon, as sugar, be present, *Penicillium* has the power of obtaining its nitrogenous constituents from humus, which must therefore be regarded as a source of nitrogen for soil organisms.

FERMENTATION—BACTERIOLOGY.

The bacterial air flora of the semidesert region of New Mexico, J. WEINZIRL (*Jour. Cincinnati Soc. Nat. Hist.*, 19 (1900), No. 7, pp. 211-242, figs. 4; *Science*, n. ser., 12 (1900), No. 303, pp. 578, 579).—A study of the air flora of the semidesert region of New Mexico was made by exposing petri plates for 10 minutes. The number of plates exposed at one time was usually 3, the results given being averaged. Seventeen exposures were made near the University of New Mexico between September and May. An average number of bacteria falling upon the plates was 35.8. The lowest number, 3.8, was observed in February, and the highest, 71, in September. Quantitative determinations were made of the bacteria, and 11 determinations gave 143 bacteria per cubic meter. The bacteria found represented 14 species, 6 of which were chromogenetic. Four of these are micrococci, the remaining colonies being all bacilli.

The conclusions reached are as follows:

“(1) The air bacteria of our semidesert region presents a somewhat limited flora; but this is found to be widely distributed, due undoubtedly to the high winds which sweep uninterruptedly over our wide stretches of nearly barren mesas.

“(2) The actual number of bacteria contained in the air is not as large as in fertile and cultivated regions, but the number is not as small as is popularly supposed.

“(3) It would seem to follow from the above that sanitary measures and precautions should receive practically the same attention here as elsewhere. Disease-bearing materials, such as infected clothes, sputum, etc., should be carefully disinfected or burned.

“(4) Many of the species show highly-colored colonies; these belong mostly to the group of micrococci. The flora is characterized by its inertness toward sugar media and its failing to peptonize gelatin.

“(5) Apparently none of the species have been previously described.”

The influence of the temperature of liquefied air on bacteria, A. MACFADYEN and S. ROWLAND (*Proc. Roy. Soc. [London]*, 66 (1900), Nos. 420, pp. 180-182; 430, pp. 339, 340).—Experiments are reported in which 10 species of bacteria were exposed for 20 hours to the temperature of liquefied air ranging from -182 to -190° C. The cultures of the organisms were vigorous and were tested in both solid and fluid media. After they had been exposed to the temperature of the liquefied air, they were carefully thawed and examined. In no instance, whether on solid or liquid media, could any impairment of the vitality of the micro-organisms be detected. A second experiment was performed in which 50 liters of laboratory air, taken about 6 ft. from the floor, were liquefied, the temperature reaching about -210° C. Plate cultures were made from the contents of the bulb which had contained the liquefied air and were grown for a period of 10 days. The anaërobic plate cultures remained sterile while the aerobic plates yielded 44 organisms which had survived the exposure to -210° C.

In a second paper on this subject the authors, instead of exposing

a media in which the bacteria were growing to the temperature of the liquefied air, submitted the organisms to a cooling process in the form of broth emulsion in hermetically-sealed tubes. In this experiment the tubes were kept practically at -190° C. for 7 days; after which they were carefully thawed, opened, and the contents transferred to suitable culture media. The organisms employed were *Bacillus typhosus*, *B. coli communis*, *B. diphtheriæ*, *B. proteus vulgaris*, *B. acidi lactici*, *B. anthracis* (sporing culture), *B. phosphorescens*, *Spirillum cholerae asiatica*, *Staphylococcus pyogenes aureus*, a *Sarcina*, a *Saccharomyces*, and unsterilized milk. Cultures made at the conclusion of the experiment grew well, and in no instance could any impairment of the vitality of the organism be detected. In one or two instances growth was slightly delayed, an effect which might have been due to other causes. The photogenic bacteria grew and emitted light, and the samples of milk became curdled.

Effect of different degrees of light on the multiplication of water bacteria, F. T. BIOLETTI (*California Sta. Rpt.* 1898, pp. 174-177).—In order to throw light upon the question of whether the water of a storage reservoir could be best conserved from bacterial contamination by exposure to the direct sunlight, or by being roofed over to exclude the direct sun rays, or by being completely covered so as to leave the water in darkness, the author undertook a series of experiments in which samples of water were taken from the inlet of the reservoir, placed in glass dishes, 10 in. in diameter and 4 in. in depth, and kept under different conditions, viz, exposed to the direct sunlight, exposed to diffused light only, kept in a dark cupboard, covered with a thin layer of crude petroleum, and alum and lime or alum and salt added to precipitate the material in the water. In the latter cases the dishes were kept in diffused light. The bacterial content of different samples was determined at intervals, the number of bacteria in a cubic centimeter being shown in tabular form. The experiments showed that there was little difference in the bacterial content of the impure water, whether exposed to direct sunlight or kept in darkness, though what little difference there was was in favor of the sunlight. The effect of direct sunlight on certain bacteria is well known, but the author doubts whether this effect will extend to the lower parts of a deep reservoir. In practice the inconvenience attending exposure to direct sunlight more than overbalances the slight gain in the prevention of bacterial growth. Where the water was kept in the direct sunlight, there were many colonies of diatoms formed and various algæ grew at the bottom. The trouble from algæ in pipes and filters makes the prevention of their growth very desirable. Where the water was covered with a slight film of petroleum, none grew.

The effect of precipitation of bacteria by means of small quantities of alum and lime was quite marked. Impure water was rendered pure

and in one case very pure. The decrease of bacterial content reaches its maximum between 24 and 48 hours, after which there is a marked increase. This has an economic bearing, showing that where this method of purification is used on a large scale it is necessary to treat small quantities of water in separate reservoirs, to be used within the following day.

Fermentation of galactose, F. DIENERT (*Ann. Inst. Pasteur*, 14 (1900), No. 3, pp. 139-189).—Researches on the fermentation of galactose and the accustoming of yeasts to this sugar are summarized by the author. The process by which the yeasts become accustomed to and capable of fermenting galactose is called by the author acclimatization. Galactose is said to be a fermentable sugar when a yeast has become accustomed to it. The duration of acclimatization varies with the different species of yeasts, being quite favored with the lactose ferments. Glucose is fermented 1.6 times more quickly than galactose by acclimatized yeasts. The required characteristic of fermentation is lost if sugar other than glucose, lactose, or melibiose be offered to the yeast.

The morphological characters of yeasts are in no way altered by acclimatization. Certain substances, such as boric acid, toluene, etc., may prevent acclimatization without preventing fermentation of glucose. When a yeast has lost its zymase by cultivation in a medium rich in peptone, it can not be made to ferment galactose until it has been revived with glucose. But, if previously acclimatized to galactose, it can be revived with that substance. During the process of acclimatization only one zymase undergoes a change of constitution, and this change is attended with profound alteration of the protoplasm. The phenomena of acclimatization is a profound modification of the condition of the cell induced by a carbohydrate closely allied to glucose. A comparison is made between yeast ferments and antitoxins, which latter not only accustom leucocytes to toxins but also act as antidotes.

The essentials of practical bacteriology: An elementary laboratory book for students and practitioners, H. J. CURTIS and M. D. LOND (*London: Longmans, Green & Co., 1900*).

The elements of general bacteriology, N. GAMALEIA (*Elemente der allgemeinen Bacteriologie*. Berlin, 1900, pp. 247).

On the structure and development of bacteria, F. VEJDovsky (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 18, pp. 577-589, pl. 1).

A critical study of the processes of denitrification, O. LEMMERMANN (*Inaug. Diss.*, Jena, 1900, pp. 91).

The physiology and morphology of alcoholic ferments, E. C. HANSEN (*Compt. Rend. Travaux Lab. Carlsberg*, 5 (1900), No. 1, pp. 1-38, figs. 5).—Studies are given on the varieties of *Saccharomyces*, in which the form of cells, formation of spores, budding, chemical action, growth in various nutrient media, and conditions of the various transformations undergone by the plant are described.

The formation of enzymes by alcoholic ferments, a specific characteristic, A. KLÖCKER (*Compt. Rend. Travaux Lab. Carlsberg*, 5 (1900), No. 1, pp. 58-63).—Studies are reported on a number of species of *Saccharomyces*, from which the author concludes that the formation of enzymes is quite constant among the different species.

Ferments and their action, C. OPPENHEIMER (*Die Fermente und ihre Wirkungen*. Leipzig: Vogel, 1900, pp. VIII+350).

Enzyms in plants, T. BOKORNY (*Naturw. Rundschau*, 15 (1900), No. 27, pp. 337-340).

The effect of liquid air on some ferments, POZERSKI (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 26, pp. 714-716).—A report is given of experiments in which the author subjected rennet, the diastase found in saliva, sucrose or invertin, amylase, inulase, trypsin and pepsin, to the action of liquid air for 45 minutes at a temperature of -191°C . Each of the experiments was repeated a number of times with new quantities of the ferments, the details of which are given. It appears from the investigation that subjecting the different ferments to the action of liquefied air at a temperature of -191°C . for 45 minutes was without effect upon their activity.

The influence of phosphates and other mineral substances on the proteolytic diastase of malt, A. FERNBACH and L. HUBERT (*Ztschr. Spiritusind.*, 23 (1900), No. 36, p. 330).

A proteolytic enzym in germinating barley, W. WINDISCH and B. SCHELLHORN (*Wehnschr. Brau.*, 17 (1900), No. 24, pp. 334-336; *abs. in Bot. Centbl.*, 84 (1900), No. 10, p. 321).—An enzym similar to trypsin was found. Its characteristics are given.

The proteolytic action of *Aspergillus niger*, G. MALFITANO (*Ann. Inst. Pasteur*, 14 (1900), pp. 420-448; *abs. in Jour. Roy. Micros. Soc. [London]*, 1900, No. 6, p. 704).—The author has determined the presence of a diastase in this fungus and has given it the name proteose. It resembles in its properties papayin and the proteolytic enzym of malt. It acts readily upon gelatin, nucleo-albumins, globulin, and albuminates, but has no effect whatever upon albumins. This last property distinguishes the proteose from pepsin, and its greater sensitiveness to alkaline phosphates distinguishes it from papayin.

A species of *Mycoderma* and its influence on beer, H. WILL (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), Nos. 17, pp. 560-565; 18, pp. 595-606).—Studies are reported upon an undescribed species of *Mycoderma* found in wort and beer.

Concerning tobacco fermentation, O. LOEW (*Centbl. Bakt. u. Par.*, 2. Abt., 6 (1900), No. 18, pp. 590-593).—A controversial article reviewing a number of published statements as to the causes of tobacco fermentation.

Remarks on the work of A. Macfadyen, G. H. Morris, and S. Rowland on expressed yeast cell plasma (Buchner's zymase), E. BUCHNER (*Ber. Deut. Chem. Gesell.*, 33 (1900), No. 17, pp. 3311-3315).

Zymase from dead yeast, E. BUCHNER (*Ber. Deut. Chem. Gesell.*, 33 (1900), No. 17, pp. 3307-3310).

METEOROLOGY—CLIMATOLOGY.

The fifth annual report for the year 1899 of the agricultural experiment station of Ploty (*Cinq. Rap. An. Sta. Eepr. Agron. Ploty*, 1899, pp. XXI+199, *dgms.* 5).—This is a detailed account (in the Russian language, with a French résumé) of the work of this station in its meteorological department, agricultural and œnological chemical laboratory, and experimental fields and vineyards. Observations on precipitation, evaporation, humidity of the air, temperature of the air and soil, cloudiness, and solar radiation have received particular attention as being of especial interest to agriculture. Observations on atmospheric pressure and wind movement are also reported. The total precipitation for the year was 404.2 mm. (but was irregularly distrib-

uted, resulting in a severe drought in winter and spring and excessive rain in summer). The precipitation at the experimental farm of the station, which is situated in a deep valley 3.5 kilometers distant from the station, was 583.2 mm. The number of rainy days at the farm was 173, as against 114 at the station. The laboratory work reported consisted of analyses of the products of the experimental farm and vineyard, tests of analytical methods, especially those for nitrogen, phosphoric acid and potash, and examinations of rain water and lysimeter drainage water. The nitrogen of rain water was found to be mainly in ammoniacal form, rarely and in very small amounts as nitrites, and still more rarely in nitrates. The ammoniacal nitrogen varied during 9 months (July to March) from 0.4 to 7 mg. per liter. Frost and fog were richest in ammonia, containing from 9 to 13 mg. The rains of July and September were richest in ammonia. In July the soil received from rain water 1,022.2 gm. of nitrogen per hectare, in September, 1,142.96 gm. The rainfall was most abundant during these months. It was found as a rule that the more copious the rainfall the lower the proportion of nitrogen. Ordinarily the first portion of the rain was richer in nitrogen than that falling later. The total amount of nitrogen carried to the soil by atmospheric precipitation during the 9 months was 4,398.6 gm. per hectare (nearly 4 lbs. per acre).

In the drainage water from the lysimeter containing bare soil, not only ammonia, but considerable quantities of nitric nitrogen, were found; while in that from soil covered with vegetation only ammonia was found. Of 246.85 gm. of ammoniacal nitrogen carried to 1 hectare of soil by 22.8 mm. of rain, only 57.37 gm. was recovered in the drainage water. It is assumed that the remaining 189.46 gm. was nitrified. Of the 505.58 gm. of ammoniacal nitrogen supplied to 1 hectare of soil by the 46.7 mm. of atmospheric precipitation during 12 days of observation, it was found that 57.37 gm. were leached out in the drainage water, and it is estimated that 189.46 gm. were nitrified and 258.75 gm. disappeared. The latter was probably partly nitrified and passed into the drainage water, and partly escaped as free nitrogen. The total amount of nitric nitrogen found in the drainage water during the same period was 8,666.49 gm. per hectare. This is equivalent to 57.57 kg. of nitrates. It is estimated that the ammoniacal nitrogen furnished by atmospheric precipitation during the year yields on an average 4,586 kg. nitrate per hectare, while at the same time the soil elaborates independently 202.9 kg. The investigations show that vegetation exercises a very decided influence in reducing the losses of nitrogen in the drainage water.

The field experiments during 1899 consisted of tests of various rotations with and without fertilizers and manure, the adaptability of various crops, and the study of the influence of vegetation and methods of culture on the temperature and humidity of the air and soil.

Deep culture (to a depth of 27 cm.) of fallows in April and May resulted in an increase of soil moisture during the whole year. The deeper the culture the more pronounced was the effect in conserving moisture. The soils were driest under green fallow. Black fallow and April fallow resulted in increased growth of crops and gave better yields than May fallow. Winter wheat on soil which had been subjected to deep cultivation was not injured by the spring drought, while summer wheat was severely injured by lack of moisture. Mulching proved to be an effective means of conserving soil moisture. Applications of manure proved injurious, soils to which manure had been applied containing considerably less moisture than that which had been mulched. The culture of low-growing plants among those of larger growth gave very unsatisfactory results. Corn following carrots gave better yields than that following beets. This is ascribed to the fact that carrots exhausted the moisture of the soil less than beets.

Work at the station of agricultural climatology of Juvisy during the year 1899, C. FLAMMARION (*Bul. Min. Agr. [France]*, 19 (1900), No. 5, pp. 868-888, figs. 11).—As in previous years (*E. S. R.*, 11, p. 819), the author reports observations on temperature of the air and of the soil at different depths, atmospheric pressure, solar radiation, rainfall, underground water, and photography of clouds. The temperature for each day of 1899 and the means for 15 years (1885-1899) are reported in tables, and results for the whole year, for the seasons, and for the 15-year period are platted and discussed in some detail. Observations on the temperature of bare and sod soils at different depths were continued during the year with results which confirm previous observations, which showed that especially in the upper layer the sod soil was warmer in winter and colder in summer than the bare soil. The sunshine recorded for the year was 1,853 hours, furnishing 147,199 calories. The total rainfall was 448.4 mm. in 1899 as compared with 539.1 mm. in 1898. The number of days on which rain fell was 98. The year was very dry, especially during the months of February, March, and November. The observations on underground waters were the same as in previous years. These observations show that the temperature of the underground water at a depth of 14 meters is higher than that of the atmosphere at that point. The photographing of clouds of different types was continued during the year. Reproductions of two such photographs are given.

Meteorological observations, J. E. OSTRANDER and C. L. RICE (*Massachusetts Hatch Sta. Met. Buls.* 142, 143, 144, pp. 4 each).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during October, November, and December, 1900. The general character of the weather of each month is briefly discussed, and the December bulletin gives a

summary for the year. The principal data in this summary are as follows:

*Pressure*¹ (inches).—Maximum, 30.75, February 28; minimum, 28.86, February 25; mean, 29.985. *Air temperature*² (degrees F.).—Maximum, 96, August 6; minimum, —8, February 3; mean, 48.3; mean sensible (wet bulb), 45; maximum daily range, 47.5, May 27; minimum daily range, 2.5, May 19; mean daily range, 21.8. *Humidity*.—Mean dewpoint, 39.2; mean relative humidity, 72.3. *Precipitation*.—Total rainfall or melted snow, 51.67 in.; number of days on which 0.01 in. or more rain or melted snow fell, 131; total snow fall, 37 in. *Weather*.—Total cloudiness recorded by sun thermometer, 2,238 hours, or 50 per cent; number of clear days, 83; number of fair days, 144; number of cloudy days, 138. *Bright sunshine*.—Number of hours recorded, 2,216, or 50 per cent. *Wind*.—Prevailing direction, W.; total movement, 50,503 miles; maximum daily movement, 435 miles, February 26; minimum daily movement, 1 mile, November 29; mean daily movement, 138.4 miles; maximum pressure persquare foot, 30.5 lbs., February 25, W. N. W. *Dates of frosts*.—Last, May 29; first, September 15. *Dates of snow*.—Last, April 9; first, November 9.

Meteorological summary for 1899, C. A. PATTON (*Ohio Sta. Bul. 120, pp. 249-261*).—This summary includes notes on the weather and tabulated daily and monthly records of observations at the station at Wooster, Ohio, on temperature, precipitation, cloudiness, direction of the wind, etc., and for comparison similar data for previous years and for other parts of the State. The following is a summary of results:

Summary of meteorological observations in Ohio.

	For the experiment station.		For the State.	
	1899.	Average for 12 years.	1899.	Average for 17 years.
Temperature (°F.):				
Mean	49.5	49.1	51.5	50.7
Highest	(Aug. 20) 95	(Aug. 8, 1891) 99	(Sept. 6) 105	(July 4, 1897) 113
Lowest	(Feb. 10) —21	(Feb. 10, 1899) —21	(Feb. 10) —39	(Feb. 10, 1899) —39
Mean daily range ..	22.9	20.5		
Greatest daily range.	(Oct. 24) 52	(Oct. 6, 1895) 55		
Clear days	126	120		
Cloudy days	125	118		
Days rain fell	116	125	107	120
Rainfall (in.):				
Greatest monthly ...	(Sept.) 5.56	(July, 1896) 8.05		
Least monthly	(Aug.) 0.53	(Sept., 1897) 0.29		
Mean yearly	32.93	39.18	34.51	37.88
Prevailing direction of wind	S.	S.	SW.	SW.

Report of the meteorologist, N. HELME (*Rhode Island Sta. Rpt. 1900, pp. 347-364*).—This includes general notes on the weather during the year ended June 30, 1900, and a tabulated record of observations at Kingston on temperature, precipitation, cloudiness, and prevailing winds during each month from July, 1899, to June, 1900, inclusive, with a summary for the year ended June 30, 1900. The latter summary is as follows:

Temperature (degrees F.).—Maximum, 90, May 15, 1900; minimum, —5, February 27, 1900; mean, 48.3; highest monthly mean, 69.5, July, 1899; lowest monthly mean,

¹ Reduced to freezing and sea level.

² In ground shelter, 51 ft. below level of other instruments.

27.8, February, 1900; highest daily mean, 77, July 27, August 19 and 20, 1899; lowest daily mean, 7.5, February 27, 1900. *Precipitation* (inches).—Total (rain and melted snow), 51.67; greatest monthly, 7.26, September, 1899; least monthly, 1.21, June, 1900; greatest in 24 consecutive hours, 4, September 20, 1899; snow fall—total, 22; greatest monthly, 9, January, 1900; least monthly, 5, March, 1900. *Weather*.—Number of clear days, 141; number of fair days, 113; number of cloudy days, 111; number of days on which there was precipitation of 0.01 in. or more, 102. *Prevailing wind*, west.

Report of the international meteorological committee, St. Petersburg, 1899 (*Meteor. Council [Great Britain] Off. Doc. 148, 1900, pp. 110*).—This report gives an account of the proceedings and the papers presented at a meeting of this committee at St. Petersburg, Russia, under the auspices of the Imperial Academy of Sciences, September 2 to 7, 1899. The papers and reports presented were as follows: Report of the magnetic conference, by A. W. Rücker; Report of the proceedings of the cloud committee, by H. H. Hildebrandsson; Report of the proceedings of the international aeronautical committee, by H. Hergesell; Report on the experiments carried on in the atmosphere by unmanned balloons and kites at the observatory of dynamical meteorology at Trappes, by L. Teisserenc de Bort; Report on the exploration of the atmosphere by kites at the observatory of Blue Hill and other stations in America, by A. L. Rotch; The aeronautical scientific experiments at Berlin, by R. Assmann; Report on radiation, by J. Violle; Meteorology and seismology, by J. Milne; Report on the German expedition to the Antarctic regions, by von Drygalski; Report on the establishment of observatories at the centers of action of the atmosphere, by H. H. Hildebrandsson; The verification of alcohol thermometers, by Rykatcheff; The influence of the stray currents, from electric tramways, on the instruments for measuring terrestrial magnetism (illus.), by J. Edler; The publication of tables of the diurnal range of temperature, in the form of deviations of the hourly from the daily means, by J. Hann; Actinometry, by J. Hann; The installation of anemometers on level ground under identical conditions, by L. Teisserenc de Bort; The use of the wet and dry bulb thermometers at stations of the second order, by J. M. Pernter; On the cable to Iceland, by Paulsen; Explanatory notes on the proposal made by von Bezold and Neumayer with reference to the publication of ten-day reports of the weather; Proposed subcommittee to consider the improvement of the telegraphic weather service, by J. M. Pernter; and Results of the international simultaneous magnetic observations of February 28, 1896 (illus.), by A. Schmidt. A very complete bibliography of radiation is given in connection with the report on that subject by J. Violle, and of hygrometry in connection with the paper on wet and dry bulb thermometers by J. M. Pernter. A list of the publications issued under the authority of the Meteorological Council of Great Britain is also given.

West Indian hurricanes, E. B. GARRIOTT (*U. S. Dept. Agr., Weather Bureau Bul. H, pp. 69, charts 7*).—"This paper reviews the writings of the more prominent meteorologists of the nineteenth century, so far as they refer to the tropical storms of the North Atlantic, and presents a chronological list of West Indian storms for 400 years. It graphically illustrates and describes the more important hurricanes that have occurred during the last 25 years, and contains accounts, based upon local records and observations, of historical storms of the West Indies."

Prevention of hail storms by cannon, J. C. COVERT (*U. S. Consular Rpts., 65 (1901), No. 245, pp. 231-235, figs. 2*).—This is an account of observations made during a visit to the towns of Bois d'Oingt and Dénicé, in the south of France, where the method of cannonading to prevent hailstorms, described by Vermorel (*E. S. R., 12, p. 316*), is practiced. The belief of the wine growers in the efficacy of this method, as demonstrated by experience during 1900, is stated to be emphatic.

Climatological table for the British Empire for the year 1899 (*Symons' Mo. Meteor. Mag.*, 35 (1900), No. 419, pp. 163, 164).—This is an annual summary of monthly climatological tables prepared from observations in all parts of the British Empire. The summary of the data reported is as follows: Highest temperature, in shade, 113.6° F., Adelaide, February 12; lowest, -46.5°, Winnipeg, February 8; greatest range, 135.9°, Winnipeg; least range, 21°, Grenada; highest mean temperature, 81.9°, Colombo, Ceylon; lowest mean temperature, 34.2°, Winnipeg; lowest mean humidity, 59°, Adelaide; highest mean humidity, 79°, Colombo, Ceylon; highest sun temperature, 175.7°, Adelaide; lowest, -16.5°, at Toronto; greatest rainfall, 73.52 in., Colombo, Ceylon; least rainfall, 17.87 in., Malta; greatest cloudiness, 5.7, Mauritius; least cloudiness, 2.3, Grenada.

Meteorological observations, A. O. LEUSCHNER and Y. KUNO (*California Sta. Rpt. 1898*, pp. 231, 232).—This is a synopsis of observations at Berkeley on atmospheric pressure, temperature, precipitation, relative humidity, cloudiness, and direction of the wind during the 2 years ended June 30, 1899.

Meteorology of lower California, G. EISEN (*Bul. Amer. Geogr. Soc.*, 1900, No. 5, pp. 397-429).—This is a part of an article on Explorations in the central part of Baja California, noted in *Science*, 13 (1901), No. 319, p. 233.

Meteorological record for 1899 (*New York State Sta. Rpt. 1899*, pp. 467-478).—Tables give a summary of monthly precipitation at Geneva, N. Y., during 18 years, 1882-1899, and daily and monthly records of the direction of the wind during 1899, and of the temperature during 1899, and during 10 years, 1890-1899.

The meteorological year, 1900, F. MARIÉ-DAVY (*Jour. Agr. Prat.*, 1901, I, No. 5, pp. 149-151).—A quarterly and annual summary of observations at the Montsouris Observatory on atmospheric pressure, temperature, humidity, cloudiness, and winds is given, and the general features of the weather of the year are discussed.

Meteorological observations (*Rpt. Cawnpore Expt. Farm, 1899-1900*, App., pp. 2a-4a).—Tables give summaries of observations at the Cawnpore Farm, near Cawnpore City, on rainfall and temperature during the year ended May 31, 1900.

Meteorology of the Ordovician, F. W. SARDESON (*Amer. Geol.*, 26 (1900), No. 6, pp. 388-391, fig. 1).

Rainfall at Emerald, Queensland (*Queensland Agr. Jour.*, 7 (1900), No. 6, pp. 499, 500).—Monthly summaries for the period from 1887 to 1900, inclusive, are given.

Rainfall conditions of the Grand Duchy of Baden, C. SCHULTHEISS (*Beiträge zur Hydrographie des Grossherzogthums Baden. Karlsruhe: Central Bureau of Meteorology and Hydrography of Baden*, 1900, No. 10, pp. 40, figs. 3, charts 15, dgm. 8).—This is a second revision, based on observations during 1888 to 1897. Detailed data are given in tables and illustrated in charts and diagrams. The organization of the service and the apparatus and methods used are explained.

AIR—WATER—SOILS.

Soils, lands, and soil moisture, E. W. HILGARD and R. H. LOUGHRIDGE (*California Sta. Rpt. 1898*, pp. 31-98, figs. 14).—This includes reports on the examination of samples of soil from different parts of California, and studies of the endurance of drought in soils of the arid region and of moisture in California soils during the dry season of 1898. The investigations on endurance of drought in soils of the arid region have already been noted (*E. S. R.*, 10, p. 617). Determinations of the moisture content of various kinds of soils to a depth of 4 ft. in

different localities in California during the dry season of 1898 are reported. The averages of these determinations for the different agricultural regions of the State are given in the following table:

Average percentages of moisture in California soils during the dry season of 1898.

	Total.	Free. <i>a</i>
	<i>Per cent.</i>	<i>Per cent.</i>
Foothills, 10 soils.....	9.7	2.6
Sacramento Valley, 23 soils.....	9.7	2.8
San Joaquin Valley, 19 soils.....	8.2	4.4
Coast Range, 44 soils.....	9.3	3.2
Southern California, 26 soils.....	6.8	2.6
State at large, 121 soils.....	8.7	3.1

a "Over and above what is held in the hygroscopic condition."

The following table shows the relative demands for total moisture by various crops on different kinds of soil:

Relative demands for moisture by crops on different soils.

	Hygroscopic moisture.	Total moisture.			Crops which did well.	Crops which suffered.
		<i>Per cent.</i>	<i>Per cent.</i>	<i>Tons per acre.</i>		
Sandy soils.....	1-3		2.0	160	Apricots, saltbush.....	Olives, peaches, plums, grapes.
			2.5	200	Olives, peaches, wheat..	Cherries, pears.
			3.5	280	Saltbush.....	Citrus, prunes.
			4-5	400	Apricots.....	Apricots.
Sandy loam soils..	3-5		5-6	480		Prunes.
			6-7	560	Almonds, plums.....	
			7-8	640	Apples, olives, peaches, walnuts.	
			8-9	720	Saltbush.....	Apricots, almonds.
Loam soils.....	5		4-5	400	Apricots, citrus, figs, walnuts.	
			5-6	480	Prunes, grapes.....	Prunes.
			6-7	560	Plums.....	Almonds.
			7-8	640	Apples.....	Peaches, plums.
Clay loams.....	5-7		8-9	720	Almonds.....	Wheat.
			9-10	800		Sugar beets.
			6-7	560	Peaches, grapes.....	Figs.
			7-8	640	Apricots.....	
Clay soils.....	7-10		8-9	720	Grapes.....	Wheat.
			9-10	800		Citrus.
			10-11	880		
			11-12	960	Corn, sugar beets.....	
			12-14	112		

NOTE.—The absence of a crop from a group simply indicates that it had not been found growing upon that particular soil.

"While the above table is interesting and useful in indicating the total amount of water required continually by crops on the various soils, and that as the soil increases in clayeyness the amount increases, because of the attraction for water on the part of the clay (hygroscopic), it is not a guide in determining the actual amounts required for particular cultures. This is found by eliminating the hygroscopic moisture and ascertaining the amount of free water present in soils where cultures grew and where they suffered, and comparing the results. This is shown in the following table, from which are omitted all determinations where no free water existed, as cultures very naturally suffered under such conditions, though maintaining life.

Amount of free water required by different crops.

Free water in 4 feet soil.		Cultures doing well.	Cultures suffering.
Percent- age.	Tons per acre.		
0-1	80	Apricots, olives, peaches, soy bean.....	Citrus, pears, plums, acacia.
1-1.5	120	Citrus, figs.....	Almonds, apples.
1.5-2	160	Almonds, plums, saltbush.....	Barley.
2-2.5	200	Walnuts, grapes, eucalyptus.....	
2.5-3	240	Apples, prunes.....	Prunes.
3-4	322	Pears, hairy vetch.....	Wheat.
4-5	400	Wheat, corn.....	
5-6	480	Sugar beets, sorghum.....	Sugar beets.

"The above summary indicates that the apricot, olive, and peach do well on less water than other orchard fruits, 1 per cent of free water being sufficient if constantly present. With this amount the citrus fruits, pears, and plums were found to suffer, though the citrus trees were in good condition with a little more water. The almond seems to require about twice the water that the apricot does, while the prune was found to suffer with three times the water in which the apricot was flourishing.

"Emphasis should be placed on the fact that this free water should be present throughout the soil to the depth of 4 ft. at least, and especially around the feeding rootlets of the tree. The surface of the soil may be wet, and yet the tree may suffer if the ground below be so dry that the rootlets are not able to draw sufficient moisture. This drying out of the under soil is one of the evil effects of a severely dry season, and unless the rainfall of the succeeding winter be sufficient to penetrate to the depth of several feet and moisten the soil around the rootlets the trees will suffer almost as if no rain had fallen.

"The same is true with regard to irrigation; those who have to resort to the artificial application of water to their lands because of insufficient rainfall, should so apply it that it may reach the tree rootlets at the depth of several feet below the surface."

Alkali and alkali soils, R. H. LOUGHRIDGE (*California Sta. Rpt. 1898, pp. 99-117, figs. 2*).—A study of the accumulation of alkali in irrigated soils used for the culture of citrus fruits, and the effect of this alkali upon the growth of these fruits, is reported, which showed that after 3 years' use of an artesian water comparatively free from soluble salts (9.46 grains per gallon containing 0.64 grains sodium chlorid and 1.85 grains sodium carbonate), the soil contained 3,240 lbs. of soluble salts per acre to a depth of 3 ft.; using Lake Elsinore water, containing 98.54 grains per gallon of soluble salts (in which there were 53.62 grains of sodium chlorid and 22.89 grains of sodium carbonate), there was an accumulation in the soil of 15,160 lbs. of alkali per acre, while in unirrigated natural soil there was only about 1,250 lbs. In case of the use of the lake water 1,680 lbs. of the alkali accumulated in the soil was sodium carbonate and 6,120 lbs. sodium chlorid; with artesian water there was 640 lbs. of carbonate and 360 lbs. of chlorid. The unirrigated soil contained neither of these salts.

It was observed that the citrus orchards irrigated with the Elsinore water were in bad condition and the station undertook to ascertain whether the injury to the trees was due to the effect of alkali or to

some other cause. Observations on the physical conditions of the lands, as well as the amount and distribution of the alkali, are reported and discussed. These indicate that while in many cases the injury to the trees was probably due to the direct action of the alkali, in some cases it was brought about by unfavorable physical conditions, due in part to the action of the alkali and in part to other causes. The effect of the different alkali salts on citrus trees and means of reclaiming injured orchards are explained.

Analyses of a large number of samples of alkali soils from different localities are reported.

Preliminary account of the soil survey work in North Carolina, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 21 (1900), No. 11, pp. 3-5).—A brief account is given of the progress made by the State Department of Agriculture, cooperating with the Division of Soils of this Department, in examining and mapping the soils of a district 105 miles long and 8 miles wide, reaching from Raleigh to Newbern. In this survey the surface and subsoils have been examined with reference to their general character, the size and character of the particles, and the amounts of fertilizing constituents present, and the extent and exact location of each type of soil has been mapped. The work has shown that "omitting the section immediately around Raleigh and the more or less swampy or pocosin soils farther east . . . there are three large classes of soils in the east, each class having a number of varieties." The main classes are deep sandy soil, sandy loam with clay subsoil, and fine sandy loam with clay subsoil. It is proposed to make this survey of the soils the basis for experiments to determine the fertilizer requirements of the different soil types, and two test farms have already been established for this purpose. The plan of experiment followed and the results of the first year's operations are noted elsewhere (p. 941).

The Illinois glacial lobe, F. LEVERETT (*U. S. Geol. Survey Monograph*, 38 (1899), pp. XXI+817, pls. 24, figs. 9).—This monograph reviews earlier studies, describes the plan of investigation pursued by the author, and reports in detail the results of his studies of the Illinois glacial lobe, which "formed the southwestern part of the great ice field that extended from the high lands east and south of Hudson Bay southwestward over the basins of the Great Lakes and the north-central States as far as the Mississippi Valley. It overlapped a previously glaciated region on the southwest, whose drift was derived from an ice field that moved southward from the central portion of the Dominion of Canada as far as the vicinity of the Missouri River." The physical features of the region are described and the time relations or glacial succession of the various drift sheets are discussed. The evidence for separating the Illinoisan drift sheet from the outlying

and underlying drift and also from the Iowan drift is briefly set forth. Remarkable instances of the transportation without destruction of stratification of limestone ledges occupying in some instances areas of several acres are noted. Descriptions are given of well-defined soils and weathered zones which occur between successive accumulations of drift, as well as of moraines and associated sheets of till, and there is a general discussion on the influence of the drift on drainage systems. The thickness of the Illinoian drift is estimated at from 100 to 130 ft. and its relation to the water supply is considered in detail. The essential conditions for obtaining artesian wells, as well as the occurrence of gas, are also considered. The sources of soil material are discussed and an attempt is made to classify the soils according to their origin and physical characteristics. Eight classes are recognized as follows: Residuary, boulder-clay soils, gravelly soils, sandy soils, bluff-loess soils, silts slowly pervious to water, fine silts nearly impervious, peaty or organic soils. A statement of the origin or mode of deposition and the areal distribution of these soils is given in a table and their agricultural value and importance are discussed. The loess soils are of particular interest. Typical soils of this class are found bordering the rivers of the region, merging inland into less pervious white clays, one class of which is known as gumbo. This is an adhesive clay varying in color from ash or light gray to nearly black. The black portions are heavily charged with humus. This gumbo soil contains a few small pebbles which seldom exceed half an inch in diameter. It closely resembles the gumbo of the Illinois and Mississippi River flood plains, which is deposited by flooded streams in the portions of the flood plains where there is little current. The origin of this deposit and its time relations compared with the overlying loess and the underlying till have not yet been satisfactorily worked out.

The soil zones of European Russia in connection with the salt content of the subsoils and with the character of the forest vegetation, G. VISSOTSKI (*Pochrovedenie* [*Pédologie*], 1 (1899), pp. 19-26).—It has been established that the soils of European Russia are distributed in zones in the following order, beginning at the north: (1) Podzol (siliceous) soils, (2) gray forest soils, (3) chernozem (black earth) soils, and (4) soils of the steppes—deserts. The quantity of the soluble salts in the subsoils increases in the same order. In the first zone the salts are entirely absent, in the second calcium carbonate is found, in the third calcium carbonate and gypsum, and in the last calcium carbonate, gypsum, sodium chlorid, potassium carbonate, etc. Conformably therewith each zone is characterized by a specific vegetation. The first is the region of mixed forests (fir, pine, birch, aspen, willow), the second of oak forests, the third of shrubby plants of the steppes (elder, hawthorn, spindle tree, cherry, privet, sloe, etc.), and the

fourth has the characteristic alkali lands vegetation (*Astragalus*, *Ephedra*, etc.) The importance of these facts in the practical work of reforestation is pointed out.—P. FIREMAN.

Laterites, P. A. ZEMYACHENSKI (*Pochvovedenie* [*Pédologie*], 2 (1899), pp. 117-122).—Notwithstanding the extended distribution of the laterites, information with regard to them is very limited. It is known only that they are very rich in ferric oxid (35 per cent and more). Recently M. Bauer communicated some entirely novel data concerning the nature of lateritic soils. From his analyses he concludes that in lateritic soils originating from granite and diorite, there occurs much free hydrate of alumina, so that they approach the bauxites in composition. The author does not agree with Bauer's conclusion. He analyzed two samples of lateritic soils, one from Mongon, China, and the other from the Caucasus (Chakva). The samples were treated with hydrochloric acid in three different ways: (1) By heating with 10 per cent hydrochloric acid 4 hours, (2) with acid of the same strength 10 hours, and (3) with strong hydrochloric acid (specific gravity 1.12) 10 hours on a water bath. From these experiments the conclusion was reached that in lateritic soils originating from feldspar there is present no free hydrate of alumina, and that the alumina is combined with silica and perhaps with ferric oxid.—P. FIREMAN.

On the spectrum of the more volatile gases of atmospheric air, which are not condensed at the temperature of liquid hydrogen, G. D. LIVEING and J. DEWAR (*Chem. News*, 83 (1901), Nos. 2145, pp. 1, 2; 2146, pp. 13-15).

Purification of air by soil, A. GÉRARDIN (*Compt. Rend. Acad. Sci. Paris*, 132 (1901), No. 3, pp. 157-159).

The molecular constitution of water, W. SUTHERLAND (*Phil. Mag. and Jour. Sci.*, 5. ser., 50 (1900), p. 460; *abs. in Chem. Ztg.*, 24 (1900), No. 100, *Repert.*, p. 361).—The author concludes from his investigations that steam is H_2O , ice $(H_2O)_3$, and water a mixture of $(H_2O)_3$ and $(H_2O)_2$. For the simple molecule H_2O the name "hydrol" is proposed.

Waters, E. W. HILGARD ET AL. (*California Sta. Rpt.* 1898, pp. 118-130).—This includes reports on analyses of 4 samples of creek and river water, the water of Lake Elsinore in 1890, 1891, 1897, and 1898, 16 samples of spring water, 38 of ordinary well water, 5 of artesian well water, and 8 of water from reservoirs and irrigation ditches with reference to mineral constituents, and of 7 samples of spring water and 5 of well water with reference to sanitary condition. The use of saline and alkali waters in irrigation is discussed and the conclusion is drawn that, "broadly speaking, any water unfit for domestic use on account of its saline contents should be used for irrigation only after an examination of the nature and amount of the latter. The limit usually given for drinking waters is 40 grains per gallon."

The disinfection of wells with potassium permanganate, E. DELORME (*Bul. Acad. Med.*, 1900, No. 25, pp. 643-648).

Sterilization of water by ozonized air by the method of Abraham and Marmier, F. KRULL (*Ztschr. Angew. Chem.*, 1901, No. 3, pp. 57-59, figs. 2).

The drainage and reclamation of marsh soils, GILLIAUX (*L'Ing. Agr. Gembloux*, 11 (1900), No. 5, pp. 194-213).

Soil temperature (*Rpt. Cawnpore Expt. Farm, 1899-1900, App., pp. 7a-10a*).—Summaries of observations at different depths during 1897-1900 are given in tables.

The cultivation of the soil, P. P. DEHÉRAIN (*Rev. Gén. Agron. [Louvain], 9 (1900), No. 9-10, pp. 405-412*).

The rôle of earthworms in the formation of cultivated soil, E. HENRY (*Chron. Agr. Canton Vaud, 14 (1901), No. 1, pp. 20-25*).

Acidity of upland soils, H. J. WHEELER and B. L. HARTWELL (*Rhode Island Sta. Rpt. 1900, pp. 293-327, pls. 3*).—This article summarizes the results of pot and plat experiments on this subject which were begun in 1894 and have been reported from time to time (E. S. R., 9, p. 937).

"The general conclusion drawn from the various experiments herein outlined is that the recognition of a high degree of acidity, even in the case of upland and naturally well-drained soils, is one of the most important guides to the first step which should be taken toward their amelioration. This seems to hold true largely, if not wholly, regardless of whether the benefit accruing from the use of carbonate of lime is attributable to its correcting physical, biological, or chemical conditions. The practical importance of this matter, even though it has been heretofore almost ignored or unrecognized by most American and many European agricultural chemists, would seem to have been abundantly demonstrated in this and the two former papers upon the same subject."

Richmond River soils, F. B. GUTHRIE and C. R. BARKER (*Agr. Gaz. New South Wales, 11 (1900), No. 11, pp. 1005, 1006*).—Analyses of a number of samples of the virgin soils of this region show a remarkable uniformity. The average of the analyses is: Capacity for water 52 per cent, organic matter (humus) 16, lime 0.21, potash 0.08, phosphoric acid 0.3, and nitrogen 0.3 per cent. The reaction is neutral to acid. The general treatment of the soils is briefly discussed.

Note on the soil of County Camden, New South Wales, F. B. GUTHRIE and C. R. BARKER (*Agr. Gaz. New South Wales, 11 (1900), No. 12, p. 1123*).—The average results of examinations of about 80 samples of soils of this county, which are derived mainly from sandstone, are as follows: Capacity for water 49.73 per cent, organic matter (humus) 11.23, lime 0.113, potash 0.102, phosphoric acid 0.171, and nitrogen 0.231 per cent. The soils vary from light sandy loam to clay loam, their reaction from neutral to strongly acid. Forty-two per cent of the soils examined were strongly acid.

FERTILIZERS.

The manurial value of the excreta of milch cows, W. S. SWEETSER (*Pennsylvania Sta. Bul. 54, pp. 7*). A record was kept of the amount and composition (nitrogen, phosphoric acid, and potash) of food eaten and of feces and urine excreted and milk produced by 2 cows, during the last 10 days of 5 periods of 40 days each. One cow was fed the same ration of 15 lbs. of mixed hay, 3 lbs. cotton-seed meal, 2 lbs. linseed meal, 2 lbs. corn meal, and 1 lb. buckwheat middlings, with a nutritive ratio of 1:3.9 throughout the experiment; with the other cow the same materials were used but the proportions were varied so that the nutritive ratios were 1:3.9 in the first and fifth periods, 1:6.1 in the second and fourth, and 1:8.7 in the third.

The total amount of nitrogen, phosphoric acid, and potash excreted by the 2 cows during the whole 5 periods in feces, urine, and milk.

with the percentage distribution of these constituents, are shown in the following table:

Fertilizing constituents in excreta and milk of 2 cows during 50 days.

	Nitrogen.		Phosphoric acid.		Potash.	
	Pounds.	Per cent of total excretion.	Pounds.	Per cent of total excretion.	Pounds.	Per cent of total excretion.
Feces	21.46	31.11	15.45	75.55	7.14	15.58
Urine	36.07	52.33	.29	1.42	34.19	74.56
Milk	11.39	16.53	4.71	23.03	4.53	9.86
Total	68.92	100.00	20.45	100.00	45.86	100.00

Summarizing these results, the bulletin states:

"(1) The feces from milch cows contain about one-third of the nitrogen, three-fourths of the phosphoric acid and one-sixth of the potash of the food.

"(2) The urine contains one-half of the nitrogen, almost no phosphoric acid, and three-fourths of the potash of the food.

"(3) The milk contains less than one-sixth of the nitrogen, one-fourth of the phosphoric acid, and one-tenth of the potash, or less than one-sixth of the manurial values of the food.

"(4) When the urine is allowed to run to waste, more than one half of the manurial value of the food, or 63 per cent of the manurial value of the solid and liquid manure, is lost."

Denitrification of nitrate of potash under the influence of reducing substances. M. KNOVALOV (*Izv. Moscov. Selsk. Khoz. Inst.*, 6 (1900), pt. 1, pp. 62-65).—This is a report of a study of the possibility of denitrification occurring without the intervention of micro-organisms, *i. e.*, under the influence of various reducing substances which occur in soil.

The first experiments were made with ferrous sulphate compounds which sometimes occur in the soil. Fifteen grams of nitrate of potash and 15 gm. of crystalline ferrous sulphate were dissolved in 300 cc. of water. Into this solution a current of air at 60 to 70° C. was led and afterwards passed through dilute sulphuric acid. Tests of the latter by means of Nessler's reagent showed that ammonia was slowly but invariably formed at ordinary temperatures.

All other experiments were made with humus. The latter was prepared from cane sugar by Berthelot's method.¹ The humus showed a scarcely perceptible acid reaction (to litmus) and contained 80 to 85 per cent of water, but no nitrogen.

The first tests were merely qualitative. Into each of two flasks were introduced 300 cc. of water, 15 gm. of nitrate of potash, and 15 gm. of humus. One flask was sterilized with water vapor at 100° C., the other by the addition of 0.4 gm. of corrosive sublimate. The stop-

¹ Ann. Chim. et Phys., 6. ser., 25 (1892), p. 366.

pered flasks stood at the temperature of the room 3 months. After the lapse of this period of time the presence of ammonia in each of the flasks was proved by Nessler's reagent. Nitrous acid was not found.

For a quantitative estimation of the ammonia formed four series of experiments were made:

(1) Ten flasks were charged as follows: To 200 cc. of water, 30 gm. of humus and 5 gm. of nitrate of potash were added. Each flask was sterilized with steam at 100° in three operations (1 hour on each of 3 successive days). The flasks were closed with a layer of cotton and a cork stopper and sealed with wax.

(2) Ten flasks were charged as before, but sterilized by the addition of 0.4 gm. of corrosive sublimate. The stoppered flasks were sealed with paraffin.

(3) Control experiments were made with two flasks containing 5 gm. of nitrate of potash and 200 cc. of water each, one sterilized, the other not, and with three flasks containing 30 gm. of humus in 200 cc. of water, one sterilized with steam, another with corrosive sublimate, the third not sterilized.

(4) Tests of the influence of caustic alkali, heating, air, and sand on the amount of ammonia formed.

Three Erlenmeyer flasks (large) received as much sand (washed and ignited) as was required to absorb 200 cc. of water with 30 gm. of humus and 5 gm. of nitrate of potash. The fourth flask received the same amount of sand, 200 cc. of water, and 300 gm. of humus. The first flask was sterilized with steam, the second with corrosive sublimate, and the third and fourth were not sterilized. All four flasks were closed with rubber stoppers carrying glass tubes through which air which had been drawn through sulphuric acid and cotton was passed from time to time (10 minutes each day).

In the fifth flask were placed 200 cc. of water, 30 gm. of humus, and 5 gm. of nitrate of potash, and 20 cc. of concentrated caustic soda. In the sixth flask the usual mixture was placed: 200 cc. of water, 30 gm. of humus, and 5 gm. of nitrate of potash. The flask was sterilized over an hour and was immediately examined for ammonia. The seventh flask was charged like the sixth, but was not sterilized. It was immediately examined for ammonia.

The determination of ammonia was made as follows: One-half of the liquid was placed in a distilling flask, a concentrated solution of caustic soda was added, and the mixture distilled. The distillate was collected in a standard solution of sulphuric acid and the excess of the latter titrated with caustic baryta. The indicator used was rosolic acid. In some cases ammonia was determined colorimetrically by means of Nessler's solution in order to avoid the heating of the mixture.

The flasks of series 1 and 2 were examined after standing 3 months.

Some of the sterilized solutions were tested for bacteria, but none were found. The amounts of ammonia found were as follows:

Amounts of ammonia found in different solutions (series 1 and 2).

	Series 1.	Series 2.
	<i>Grams.</i>	<i>Grams.</i>
No. 1	0.00220	0.001519
No. 200038	.000656
No. 3a00045	.000288

a By Nessler's reagent without distillation.

Series 3 (control experiments) was examined after 2 to 4 months. No ammonia was found.

The results obtained in series 4 were as follows:

Ammonia found in series 4.

Ammonia.		Ammonia.	
<i>Grams.</i>		<i>Grams.</i>	
No. 1, examined after 48 days	0.001295	No. 5, examined after 15 days	0.0001899
No. 2, examined after 45 days000379	No. 6, examined immediately after sterilization0002
No. 3, examined after 45 days000294	No. 7, examined immediately, with- out sterilization.....	None.
No. 4, examined after 48 days	None.		

In all cases the ammonia was determined without previous decomposition of the humus which, as is well known and as the author proved by special experiments, retains ammonia. The above figures for ammonia are, therefore, too low.

Without making special claims for the accuracy of the quantitative determinations the author draws the following conclusions:

(1) Humus, as well as the ferrous salts, is able to reduce nitrate of potash to ammonia.

(2) This reduction proceeds very slowly at ordinary temperatures, but becomes more rapid on heating.

(3) Caustic alkali and free access of air do not destroy the ability of humus to reduce nitrate.

(4) Thus the possibility of denitrification of nitrate of potash in the soil under the influence of humus, without bacteria, is fully corroborated by laboratory experiments.—P. FIREMAN.

Fertilizer experiments with different sources of phosphoric acid. H. J. PATTERSON (*Maryland Sta. Bul.* 68, pp. 29).—An account is here given of experiments begun in the spring of 1895 on tenth-acre plats of moderately stiff clay naturally well drained, to test the comparative availability of double superphosphate (soluble and reverted), dissolved boneblack, dissolved South Carolina rock, iron and alumina phosphate (reverted), boneblack, raw bone meal, slag phosphate, ground South Carolina rock, and Florida soft phosphate. These different phosphates were each applied in amounts furnishing 150 lbs. of phosphoric acid per acre. The bulletin gives a discussion of

phosphatic fertilizers in general and a description of the particular phosphates used in these experiments, a record of treatment and cultivation of the plats since the beginning of the experiments, and a tabular summary and discussion of the data obtained in experiments with the different phosphates on corn, wheat, rye, and crimson clover. The results are summarized as follows:

- "(1) All forms of phosphoric acid produced an increase of crop.
- "(2) The average total yield of the crops fertilized with insoluble phosphoric acid was greater than those with the soluble and reverted forms of phosphoric acid.
- "(3) Reverted phosphoric acid gave a greater total yield than soluble phosphoric acid.
- "(4) Reverted phosphate of iron and alumina gave a higher yield than reverted phosphate of lime.
- "(5) Soluble phosphoric acid gave slightly higher yields of wheat (grain) than phosphoric acid in any other form.
- "(6) Concentrated sources of soluble phosphoric acid gave better results than the low grade sources.
- "(7) Untreated South Carolina rock gave a higher total yield than dissolved South Carolina rock.
- "(8) Slag phosphate produced a greater total yield and at less cost than the average of the soluble phosphoric acid plats and the bone meal plats.
- "(9) Insoluble phosphoric acid from slag produced a greater yield than the insoluble phosphoric acid from South Carolina rock and Florida soft phosphate, but at greater cost than the two latter.
- "(10) For the best results with insoluble phosphates, it is desirable to have the land well filled with organic matter. Of the methods tested, crimson clover was the best means of obtaining this."

Commercial fertilizers, E. H. JENKINS, S. W. JOHNSON, ET AL. (*Connecticut State Sta. Rpt. 1900, pt. 1, pp. 112*).—This includes a statement of fertilizer sales in Connecticut in 1900, the text and an abstract of the State laws relating to fertilizers, a list of manufacturers securing licenses under these laws, notes on the sampling and collecting of fertilizers, explanations regarding the analysis and valuation of fertilizers, a report on determinations of the solubility of organic forms of nitrogen in pepsin-hydrochloric acid, a review of the fertilizer market for the year ended October 31, 1900, and tabulated analyses and valuations of 466 samples of fertilizing materials, including nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, castor pomace, ground fish, tankage, bone manures, dicalcium phosphate, superphosphate, muriate of potash, sulphate of potash, sulphate of potash and magnesia, kainit, carbonate of potash, nitrate of potash, cotton-hull ashes, wood ashes, limekiln ashes, crematory ashes, lime, land plaster, waste from acetylene manufacture, tobacco stems, muck, sheep manure, street sweepings, silk-mill waste. The average cost of nitrogen in 4 samples of nitrate of soda examined was 14.3 cts. per pound; in 1 sample of sulphate of ammonia, 18.5 cts.; in 44 samples of cotton-seed meal, 14.3 cts., "nearly a cent and a half per pound more than last year. This is due to an increased foreign demand for cotton-seed meal." The price per pound of nitrogen in 5 samples of castor

pomace varied from 15 to 20.1 cts. An unusually high percentage of chlorin was found in samples of sulphate of potash examined, some of these containing over 14 per cent of muriate of potash. It is recommended that this material should be purchased only on a guaranty of not over 2 per cent of chlorin. In 9 samples of muriate of potash examined the percentage of potash varied from 43.97 to 54.18, the cost per pound of the potash from 4.0 to 4.8 cts., averaging 4.3 cts. The average cost of the bone manures examined was \$27.08 per ton, the average valuation \$25.51. In 6 of the 25 brands examined the percentage of nitrogen was less than that guaranteed, in 4 the same was true of the percentage of phosphoric acid. The valuation of 4 of the 6 samples of dry fish examined was higher than the cost, "indicating that during the present year, as was also the case last year, dried fish had been a cheap source of nitrogen and phosphoric acid." Of the 90 samples of nitrogenous superphosphates examined 15 were below the manufacturers' minimum guaranty in respect to one ingredient, and 3 in respect to two ingredients. The average cost of the superphosphates was \$30, the average valuation \$19.75. Of 100 samples of special manures examined 14 did not fulfill the manufacturers' guaranty in respect to one ingredient and 2 were deficient in respect to two ingredients. The average cost of these manures was \$32.73, the valuation \$22.49. Analyses of 41 samples of cotton-hull ashes are reported.

"The highest percentage of water-soluble potash is 28.12 and the lowest 11.45. Excluding the latter—found in goods which were sold at a low price because of their inferior quality—the lowest percentage was 13.29 and the average of 40 samples was 19.89 per cent, nearly 3 per cent lower than last year.

"Allowing $4\frac{1}{2}$, 4, and 2 cts. per pound for water-soluble, citrate-soluble, and insoluble phosphoric acid, the cost of water-soluble potash, in cotton-hull ashes, has ranged from 10.9 to 5.1 cts. per pound and has averaged 7.5 cts., eight-tenths of a cent more per pound than last year."

The water-soluble potash in 19 samples of wood ashes examined varied from 2.38 to 6.09 per cent, averaging 4.32 per cent.

Most of the nitrogenous fertilizers examined during the year were tested, as to availability of the nitrogen, by the pepsin-hydrochloric acid method. The results are summarized in the following table:

Solubility of nitrogen of fertilizers in pepsin-hydrochloric acid.

Fertilizer.	No. of samples tested.	Nitrogen dissolved.		
		Maximum.	Minimum.	Average.
		Per cent.	Per cent.	Per cent.
Blood	1			84.0
Cotton-seed meal	2	91.0	89.0	90.0
Castor pomace	4	91.5	74.0	84.6
Bone	25	99.4	69.9	87.0
Tankage	5	82.8	73.1	76.3
Fish	5	87.6	61.5	73.5
Bone and potash	6	88.2	58.1	77.6
Superphosphates	90	91.7	18.9	74.8
Special fertilizers	99	100.0	57.8	76.4

"It is clear from these figures, as well as from other results previously published by this station and by other observers, that the solubility of organic nitrogen in materials generally regarded as quickly acting fertilizers, such as blood, cotton seed, castor pomace, fish, tankage, bone and the like, may range from about 60 to nearly 100 per cent.

"There is no reason to suppose that those with the lower solubility named are less effective fertilizers than those whose solubility in pepsin solution is relatively high.

"It is evident, therefore, that it would be quite possible to mix inferior nitrogenous matter, like leather, hair, etc., with its own weight of some approved form of nitrogen, which had exceptionally high solubility in pepsin solution, and produce a mixture which would not be certainly detected by the test described above. It is only when the solubility is 50 per cent, or lower, that it is reasonable to suspect the presence of inferior or inert forms of nitrogen."

On the fertilizing value of stable manure mixed with a litter of tobacco stems, N. PASSERINI (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 441-445).—Experiments are briefly reported in which tobacco stems were used as litter with stable manure, yielding a product after fermentation which had the following composition: Nitrogen 0.84 per cent, phosphoric acid 0.62 per cent, and potash 1.97 per cent, the tobacco stems supplying 0.26 per cent of nitrogen, 0.32 per cent of phosphoric acid, and 1.47 per cent of potash.

Filter-press cake as a fertilizer (*West Indian Bul.*, 1 (1900), No. 4, p. 395; *abs. in Jour. Soc. Chem. Ind.*, 19 (1901), No. 12, p. 1125).—It is stated that 1,000 lbs. of cake as obtained in the sugarhouse contains about 7 lbs. of nitrogen and 5 lbs. of phosphoric acid.

Jadoo fiber (*Jahresber. Vers. Stat. u. Schule, Wädenswil*, 1897-98, pp. 49-50).—This was found to be peat moss soaked in a solution of fertilizer material. Upon analysis it showed 9.76 per cent of nitrogen, 0.56 per cent of phosphoric acid, and 0.21 per cent of water-soluble potash.

Analyses of fertilizers, C. A. GOESSMANN (*Massachusetts Hatch Sta. Bul.* 70, pp. 26).—Analyses are reported of 231 samples of fertilizing materials, including wood ashes, sulphate of potash, muriate of potash, potash and magnesia sulphate, nitrate of soda, ground fish, cowpea and soy-bean plants, river and pond muck, sewage sludge, peat, soot, barnyard manure, sheep manure, cotton waste, product from garbage plant, tobacco stalks, bat guano, ground bone, dissolved boneblack, Florida rock phosphate, mixed fertilizers, and soils.

Fertilizer analyses, R. C. KEDZIE (*Michigan Sta. Bul.* 185, pp. 269-281).—This includes tabulated analyses, accompanied by guarantees, of 81 samples of fertilizers examined during 1900, with brief explanatory notes.

Fertilizer analyses—fall season, 1900, B. W. KILGORE (*Bul. North Carolina State Bd. Agr.*, 22 (1901), No. 1, pp. 3-16, 19-29).—This includes notes on valuation, freight rates from the seaboard to interior points, a list of fertilizers registered for 1901, and analyses and valuations of 131 samples of fertilizers. There are also included a brief report on analyses of miscellaneous fertilizing materials, including marls, wood ashes, cotton-hull ashes, compost, tobacco stems and dust, tobacco stem ashes, and barnyard manure, and a warning against a so-called manual of secret processes for the manufacture of home-made fertilizers.

Commercial fertilizers, H. J. WHEELER, B. L. HARTWELL, ET AL. (*Rhode Island Sta. Bul.* 73, pp. 39-50).—This bulletin contains analyses and valuations of 59 samples of fertilizers examined during 1900 in addition to those reported in previous bulletins (*E. S. R.*, 12, pp. 626, 737). In addition to the mixed fertilizers examined analyses are reported of 8 samples of wood ashes, 3 of muriate of potash, and 3 of nitrate of soda. A summary of the results of fertilizer inspection in the State during 1900 and previous years shows that in 1900 84.9 per cent of the fertilizers were equal to or above

the guaranty, 8.1 per cent were less than 0.3 per cent below the guaranty, and 7 per cent were more than 0.3 per cent below the guaranty, a condition not as satisfactory as that shown in 1895 and 1896, but slightly better than in 1899. The greatest discrepancies between the actual analyses and the guaranties were observed in the case of soluble phosphoric acid, for which the guaranties often exceeded the amounts actually found.

On the diffusion of nitrogen in chemical manure compounds, J. OSTERSETZER (*Chem. News*, 83 (1901), No. 2145, p. 3).—Attention is called to the fact that by the action of sulphuric acid the nitrogen of organic fertilizing materials is to a large extent converted in soluble form, including ammonium sulphate, and these nitrogen compounds are more thoroughly diffused throughout the mass of the fertilizer than is possible by mechanical means, a matter of great importance in estimating the relative value of fertilizers.

The distribution of chemical fertilizers, C. DUSSEY (*Chron. Agr. Canton Vaud*, 14 (1901), No. 1, pp. 17-20).

Analyses of lime, W. H. WEIGAND and C. G. CHURCH (*Maryland Agr. Col. Quart.*, 1900, No. 10, pp. 4-6).—Brief accounts are given of a study of the chemical composition of coal-gas lime, water-gas lime, shell lime, and unburnt oyster and clam shells.

Potassium nitrate in Wyoming, W. C. KNIGHT (*Science*, n. ser., 13 (1901), No. 317, p. 151).—The examination of samples of material found near Dayton, Wyo., which contained over 50 per cent of potassium nitrate, are reported.

The phosphates of the Florida hard rock region, C. ELSCHNER (*Chem. Ztg.*, 24 (1900), No. 101, pp. 1111-1113).—A brief review of the history of these deposits, accompanied by descriptions and analyses of the phosphates.

The potash salt mines of Stassfurt (*Rev. Gén. Agron.* [Lowain], 9 (1900), No. 9-10, pp. 412-426, pls. 2, figs. 5).—This article discusses the location and importance of the Stassfurt deposits, the character of the crude and concentrated salts, and the production and consumption of the salts.

The world's production and consumption of mineral fertilizers, L. GRANDEAU (*Jour. Agr. Prat.*, 1901, I, No. 4, pp. 117-119).—According to the figures given the total production of raw phosphate in 1899 was 2,500,000 tons, and of superphosphates in Europe, 3,505,000 tons. The greatest producers of superphosphate were France, 950,000 tons; Germany, 800,000 tons; Great Britain, 600,000 tons; Italy, 300,000 tons. The larger part of this superphosphate was consumed in the countries producing it.

FIELD CROPS.

A fertilizer experiment with barley, R. ULRICH (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 14, pp. 533-538; 15, pp. 554-558).—Thomas phosphate, kainit, nitrate of soda, and well-rotted barnyard manure were used alone and in combination for fertilizing barley on clay loam soil. The yields obtained with the different fertilizers and combinations, the profitableness of each, and their effect on the quality of the grain are shown in a number of tables. The largest and most profitable yields were obtained by the use of all 3 essential elements, as furnished by Thomas phosphate, kainit, and nitrate of soda. The water content of the air-dry grain was greater with fertilized than with unfertilized grain. The starch content increased with the addition of fertilizers and was most influenced by potash. The use of nitrogenous fertilizers increased the protein content of the grain while phosphoric acid and potash had a depressing effect.

Some varieties of winter barley, R. J. MANSHOLT (*Orgaan Ver. Oudleer. Rijks. Landbouwschool*, 12 (1900), No. 140, p. 49).—This article contains descriptions and records of trials of some varieties of barley, principally of the two-rowed and four-rowed kinds. Most of these trials were of hybrids, of which the most promising were double crosses. Two of these are particularly interesting from the fact that while they are of precisely the same parentage, one is a two-rowed and the other a four-rowed sort. They resulted from the following crosses: Groningen winter by Algerian two-rowed by Groningen winter barley. The fact that a summer barley enters into these crosses makes it doubtful whether they will endure a severe winter, but this point has not yet been tested.

The Canadian Mammoth and the English Matchless were tested but were discarded as not suited to the conditions prevailing on the experiment farm.—H. M. PIETERS.

Cooperative grass and forage plant investigations with State experiment stations, T. A. WILLIAMS (*U. S. Dept. Agr., Office of the Secretary, Circ. No. 8, pp. 14*).—Report of a visit to certain experiment stations in the West for the purpose of arranging for cooperative grass and forage plant investigations between the station and this Department through the Division of Agrostology. Cooperative experiments are suggested along the following lines: (1) The formation, care, and management of pastures, (2) range improvement, (3) alkali-resistant crops, particularly those best adapted to furnish forage that can be used to supplement the native ranges, (4) cover crops for soils liable to wash which will at the same time afford a supply of forage or can be turned under for green manure, (5) a continuous soiling series for use in sections where the dairy industry is paramount, (6) winter pasturage for the South and Southwest, (7) sand-binding grasses for the coast regions and along the Great Lakes, (8) meadow crops for higher altitudes, (9) supplementary forage crops, particularly those with a short season of growth that can be grown in rotation with wheat, cotton, and other primary crops, either for forage or for the improvement of soil fertility, (10) drought-resistant crops for arid sections, (11) the selection and development of improved varieties of grasses and forage crops adapted to special conditions and uses.

Experiment in top-dressing grass land, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul. 71, pp. 15-20*).—A detailed account of the grasses grown, manures used, and the yield obtained per acre in 1899 on the grass lands here noted was given in an earlier bulletin (E. S. R., 11, p. 641). An early drought affected the yield of grass in 1900 and only one crop of hay was secured.

The plat fertilized with 1,200 lbs. of acid phosphate and 180 lbs. of muriate of potash but no nitrogen produced 1.6 tons of barn-cured hay per acre. When 150 lbs. of nitrate of soda was added to these

fertilizers on another plat the yield was at the rate of 2.24 tons per acre. And when 450 lbs. was so added on a third plat the yield was increased to 3.28 tons. The use of the 150 lbs. of nitrate of soda resulted in increasing the financial profits \$6.94 per acre and the use of 450 lbs. in an increased value of \$16.98 per acre. It is thought that this profit might have been greater had only 350 or 400 lbs. of nitrate of soda been used.

The relative proportion of timothy hay was decidedly increased by the nitrate of soda. "This was probably due largely to the removal of the nitric acid by the plants and the lessening of the soil acidity by the soda which was thus left behind."

Early applications of nitrate of soda to force growth, by placing at the disposal of the plants when moisture in the soil is abundant an immediate supply of available nitrogen, is believed to be especially valuable for grass in seasons of drought.

Reports on various seeds and plants included in the university distribution, E. J. WICKSON (*California Sta. Rpt. 1898, pp. 236-253*).—This includes brief reports by the station and statements of farmers regarding the growth and value of a number of plants and seeds distributed by the station.

Roselle (*Hibiscus sabdariffa*) promises to be of much value for jelly-making where currants do not thrive. It makes large returns in localities wherever there is a long frostless season combined with high summer heat. The local trials of fenugreek (*Trigonella fenum-graecum*) seem to indicate that the plant endures as low temperatures as it is likely to encounter in most valley situations, and is promising as a green manuring plant. Hairy vetch (*Vicia villosa*) promises to be one of the best winter-growing plants, both for forage and green manure purposes, in California. Besides hardiness against frost, it has a marked drought resistance. The mealy saltbush (*Atriplex halimoides*) gives promise of surpassing in value even the Australian saltbush (*A. semibaccata*) on dry lands, and gives indications of being of value in so-called desert situations.

Other plants reported upon are Jerusalem artichokes, Jersey kale, oat grass, Texas blue grass, brome grasses, buffalo grass, edible pod pea, Washington market sweet corn, carrots, climbing French bean, flat pea, etc.

Note on the growth of lupines on calcareous lands, E. W. HILGARD (*California Sta. Rpt. 1898, pp. 225, 226*). This note states that in the experience of the author lupines planted in the spring have given very unsatisfactory results on clayey and sandy soils. This season a test of sowing lupines in the fall gave very good results. The soil upon which this test was made contained 35 per cent of clay and fully 1 per cent of carbonate of lime and magnesia. The results of experiments with lupines made by Heinrich (E. S. R., 8, p. 969), which

led him to conclude that 0.5 per cent of carbonate of lime or magnesia is very deleterious to the growth of lupines, are discussed, but the author believes this to be true in the case of sandy soils only. The experiments here reported showed that on heavy clay soils double that quantity of carbonate of lime or magnesia was not injurious.

Potato experiments (*Agr. Gaz.* [London], 52 (1900), No. 1390, p. 115).—The summarized results secured in 1899 by Wright at the West of Scotland Agricultural College in manuring potatoes are reported. The data given are the averages secured from 10 farms. On unmanured land the yield of potatoes was 5.02 tons per acre. When 20 tons of barnyard manure was applied, the yield increased to 7.85 tons. Where only half of this amount of barnyard manure was used, the yield was decreased 1.4 tons, and when to the full ration of 20 tons of barnyard manure was added 448 lbs. of superphosphate and 112 lbs. each of sulphate of ammonia and of potash, the yield was increased to 8.22 tons. The same amount of these commercial fertilizers used in connection with 10 tons of barnyard manure resulted in a yield of only 1,232 lbs. less than when the full application of 20 tons of barnyard manure was used. In a test of three potash manures for potatoes, the yields remained practically identical. The greatest amount of starch, however, was found in the potatoes fertilized with the sulphate. The best fertilizer, as regards economy and preparation for the succeeding crop, was that made up of 10 tons of barnyard manure, 448 lbs. of superphosphate, 112 lbs. of sulphate of ammonia, and 168 lbs. of sulphate of potash. Increased quantities of commercial fertilizers gave nearly as good yields at slightly less expense, but the value of barnyard manure for succeeding crops it is thought more than covered any slight advantage in the cheapness of the commercial fertilizers.

Experiments on potatoes in Yorkshire (*Agr. Gaz.* [London], 52 (1900), No. 1384, p. 19).—A summarized account is given of a report issued by the Yorkshire College and certain county councils on experiments with potatoes in 1899. One of the chief experiments was the test of the substitution of commercial fertilizers for a part of the barnyard manure employed in a full dressing of 20 tons. The average results secured in experiments at 5 farms show a yield of 6.38 tons per acre where no manure was applied; with 20 tons of barnyard manure, the yield was 10.54 tons per acre. Where only half this amount of barnyard manure was applied, the yield averaged 8.95 tons per acre. Where to the 10 tons of barnyard manure there was added 156 lbs. of sulphate of ammonia, 336 lbs. superphosphate, and 224 lbs. of potash salts, the yield was raised to 9.92 tons per acre. When the sulphate of ammonia was omitted in the above formula, the yield was decreased 572 lbs. When superphosphate was omitted the decrease was 1,062 lbs. per acre. The use of commercial fertilizers alone at the rate of 336 lbs. of sulphate of ammonia, 560 lbs. of superphosphate, and 224

lbs. of sulphate of potash per acre did not give as good yields as was obtained from applications of 10 tons of barnyard manure. The average increased yield obtained with full dressings of barnyard manure, as compared with half dressings and the addition of the commercial fertilizers, was due largely to the greatly increased yields secured at one station. At another station the yield from the combination was larger than from the barnyard manure alone, while at 2 other stations it was nearly as large.

The influence of water and fertilizers on the composition of the ash of the potato, A. VON DASZEWSKI and B. TOLLENS (*Jour. Landw.*, 48 (1900), No. 3, pp. 223-249).—Analyses of tubers and leaves (20 samples) of potatoes grown with little and with much water and with different kinds of fertilizers are reported and the methods used are described.

The Tucker ash apparatus (E. S. R., 11, p. 506) was used with excellent results. It was shown that the water content of the soil exerts a great influence upon the life of the potato plant and upon its assimilation of plant food. With the larger amount of moisture in the soil the potato plant took up a larger amount absolutely and a relatively smaller amount of potash and phosphoric acid than with the smaller amount of moisture, the assimilation of the potash and phosphoric acid going hand in hand. Relatively more calcium and chlorin were taken up in case of the larger moisture supply. The fertilizers influenced both yield and composition. Nitrogenous fertilizers increased the nitrogen content of both the leaves and tubers. The reduction of starch content which occurred when the larger amount of water was used was more largely influenced by calcium chlorid than by any other substance applied.

Culture of resistant, nonseed producing sugar beets, J. WENDENBUSCH (*Deut. Landw. Presse*, 27 (1900), No. 11, pp. 107-109).—Cold, wet, or otherwise unfavorable weather conditions during the early stages of growth of sugar beets tend to further the premature development of seed-bearing specimens and thus reduce the net yield of normal beets per acre. The author has attempted to meet these difficulties by growing beet seed on a cold clay upland soil where beets grown from commercial seeds even in favorable years produced a high percentage of premature seed beets. By careful selection of seed for a number of years on this cold upland soil a strain of seed has been obtained which is very resistant to cold and which, when planted under more favorable soil and climatic conditions, produced crops containing much lower percentages of premature seed beets than are obtained from seeds grown under normal conditions.

In 1899, an unfavorable season for sugar-beet culture, sugar-beet seed from 3 different seedsmen was planted in a favorable locality alongside of beet seed grown on the cold, heavy upland soils noted

above. The commercial seeds produced crops containing from 9 to 11.5 per cent of premature seed specimens, while the seed grown on the cold, upland clay produced a crop containing but 2.7 per cent of premature seed specimens. The results of the investigation are thought by the author to have an important bearing on the beet-sugar seed industry.

Tobacco culture experiments in Russia, P. LOMONOSOV (*Rpt. Tobacco Expt. Sta. Lokhvits Agr. Soc. 1893, 1894, and 1895, pp. IV + 116*).—This report on tobacco work near Lokhvits, Government of Poltava, in southern Russia, is introduced with a general discussion of tobacco culture in that region. The work here described consisted of plat experiments with the commonly grown variety known as Makhorka and considered as yielding a leaf of good quality. The soil on which the experiments were carried out was the typical valley chernozem common to that section of Russia. The upper 18 in. of the soil is somewhat sandy and dark gray in color, the next 28 in. is light gray, somewhat yellowish, and contains carbonates, and the subsoil is a light gray loess. The results showed that decreasing the distance between plants increased the yield but decreased the weight of the leaf and of the entire plant and was detrimental to the quality. The best distances were 21 by 14 and 21 by 10½ in. When planting 21 by 14 in. apart it is recommended to leave 7 or 8 leaves per plant. This increases the yield 40 per cent as compared with the usual practice of leaving from 4 to 6 leaves. The same results may be obtained by planting 21 by 10½ in. apart and leaving 6 leaves per plant. Watering the young plants proved beneficial. Starting tobacco directly in the field without the preliminary growth of the plants in hotbeds is considered profitable only when atmospheric conditions are favorable. A large number of leaves per plant, close planting, and frequent watering and cultivating delayed maturity. The average loss of weight in curing the leaves was 75.62 per cent.

The basis for the improvement of American wheats, M. A. CARLETON (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 24, pp. 87, pls. 10, figs. 5, map, 1*).—This bulletin describes the characteristics and needs of the several wheat districts in the United States, and suggests how the desired qualities to satisfy these needs may be obtained. The characteristics of the different botanic groups of wheat are considered according to the following classification: *Triticum vulgare*, *T. compactum*, *T. durum*, *T. turgidum*, *T. polonicum*, *T. spelta*, *T. dicoccum*, and *T. monococcum*. In general it is stated *T. vulgare*, *T. polonicum*, and *T. monococcum* are considered as species, while the rest are ranked as subspecies. The desirable and undesirable qualities of the several groups are enumerated.

The author divides the United States into eight different wheat growing districts. In the soft wheat district, including mainly the

Middle and New England States, the chief varieties grown are Fultz, Fulcaster, Early Genesee Giant, Mediterranean, Early Red Clawson, Longberry, Jones Winter Fife, Red Wonder, Gold Coin, and Blue Stem, and the present average yield is about $14\frac{2}{3}$ bu. per acre. The semihard winter wheat district, comprising Ohio, Indiana, Illinois, Michigan, and a small part of Wisconsin, grows chiefly Fultz, Poole, Rudy, Valley, Nigger, Dawson Golden Chaff, and Early Red Clawson. The average yield per acre for the district is about 14 bu. The southern wheat district, including approximately the Southern States, has an average yield per acre of about $9\frac{1}{2}$ bu., the varieties commonly grown being Fultz, Fulcaster, Red May, Rice, Everett High Grade, Boughton, Currell Prolific, and Purple Straw. The northern portion of the States of the plains constitutes the hard spring wheat district, with an average yield per acre of about 13 bu., and with Saskatchewan Fife, Scotch Fife, Powers Fife, Wellman Fife, Hayne Blue Stem, and Bolton Blue Stem as the chief varieties grown.

The hard winter wheat district covers the central portion of the States of the plains. The average yield per acre in this district is about $12\frac{2}{3}$ bu., and the chief varieties grown are Turkey, Fulcaster, May, Zimmerman, and Fultz. In the durum wheat district, which covers the southern portion of the States of the plains, the chief varieties grown are Mediterranean, Nicaragua, Fulcaster, and Turkey, the average yield being $11\frac{1}{2}$ bu. per acre. The irrigated wheat district, comprising approximately the Rocky Mountain and Basin States, shows the highest average yield per acre, about 21 bu., with Sonora, Taos, Felspar, Little Club, Defiance, and Amethyst as the chiefly grown varieties. The white wheat district has an average yield per acre of about $14\frac{1}{4}$ bu., and Australian, California Club, Sonora, Oregon Red Chaff, Foise, Palouse Blue Stem, Palouse Red Chaff, White Winter, and Little Club are the chief varieties.

In all districts, except in the semihard winter wheat district, early maturity is a quality to be sought. Hard winter varieties are needed everywhere except in the southern, durum, and irrigated wheat districts. Rust resistant varieties are needed in the soft, semihard winter, southern, hard spring, and durum wheat districts. Harder grained and glutinous varieties are required in the soft wheat district, semihard winter, and irrigated wheat districts. Drought resistance is a quality especially required for varieties in the hard spring, hard winter, and durum wheat districts. The author further mentions macaroni varieties needed in the durum wheat district, nonshattering varieties in the white wheat district, and varieties resisting late spring frosts and with an increased stiffness in the straw in the southern wheat district.

An outline of the geographic distribution of wheats of different qualities is also given. The work of improvement, which is continu-

ously carried on, and the results that have already been attained in various ways by the Department of Agriculture, and other agencies, are discussed. A comparative résumé of the principal qualities of 245 representative wheats of the world, grown experimentally by the Department of Agriculture, are presented in a table.

First report of work on the department's test farms for the season 1900, B. W. KILGORE ET AL (*Bul. North Carolina State Bd. Agr.*, 21 (1900), No. 11, pp. 6-53, pls. 6).—The work described comprises fertilizer and other tests with corn, cotton, potatoes, sweet potatoes, grasses, and leguminous plants carried on at Tarboro and Red Springs farms. An outline of the methods and purposes of the tests is given.

The experiments with corn showed nitrogen to be most needed in the soil, but, in general, its cost made the increased yield expensive. Applying one-half the nitrogen in the form of cotton-seed meal at planting time and the rest during the growing season gave good results, but substituting nitrate of soda for cotton-seed meal as an after dressing proved more effective. Comments are given on all the results, but general conclusions are reserved on account of insufficient data. A paper on Leguminous plants for forage and soil improvement, by J. F. Duggar, read at a meeting of Commissioners of Agriculture of the cotton States is reproduced.

Collection and distribution of grass seed—field work (U. S. Dept. Agr., *Office of Secretary Circ. 9*, pp. 11).—This circular is a brief report to the Secretary of Agriculture on the work of the Division of Agrostology in the direction of purchasing and collecting seeds and specimens of valuable economic grasses and forage plants for the purpose of distributing them to the various experiment stations, and of the field work for the season of 1900. The work was in charge of C. L. Shear of that Division. A list of particularly promising grasses of which seeds were secured in quantity is given and the merits of each species briefly noted. This list comprises dry meadow and range grasses, wet meadow grasses, soil and sand binding species, and alkali soil and subalpine species.

Frost injury to crops and methods of its prevention, A. TRAMPE (*Landw. Ztschr. Rheinprovinz*, 1 (1900), No. 22, pp. 255, 256).—An article describing in a popular manner the culture of fall grains and calling attention to the importance of the variety of grain, kind of seed, and manner of sowing, and the fertilization and preparation of the soil, in resisting cold winters.

Investigations on the stooling of grains, W. RIMPAU (*Landw. Jahrb.*, 29 (1900), No. 4-5, pp. 589-628, figs. 3).—This article is a translation of a report on experiments by E. Schribaux, and a series of controversial letters on the subject which appeared in the *Journal d'Agriculture Pratique*.

Of what value is the stooling of grains? EDLER (*Fühling's Landw. Ztg.*, 49 (1900), Nos. 22, pp. 850-852; 23, pp. 871-876).—A discussion of Schribaux's work, published originally in the *Journal d'Agriculture Pratique*.

Methods of growing barley of a low nitrogen content for brewing purposes on light soils, T. REMY (*Centbl. Agr. Chem.*, 29 (1900), No. 12, pp. 809-811).

Chicory growing, M. G. KAINS (U. S. Dept. Agr., *Division of Botany Circ. 29*, pp. 12, figs. 3).—A popular publication on the culture of chicory for its various uses. A bulletin on this subject by the same author is abstracted in E. S. R., 10, p. 236.

Cotton monograph; culture, economic history, H. LECOMTE (*Le coton monographie; culture, histoire, économique*. Paris: Georges Carré & C. Naud, 1900, pp. 494, figs. 37).—Part 1 treats comprehensively of the history, botany, and physical and chemical character of cotton, cotton by-products, culture of cotton in the United States and other American countries, diseases and insects affecting cotton culture in Egypt and other countries of Africa, in Europe, and Asia. Part 2 discusses the cot-

ton industry and treats of the uses of cotton, and of the progress of the cotton industry in different countries of the world. A bibliographical index is given, which contains a list of 137 papers, books, etc., on cotton.

Hops in their botanical, agricultural, and technical aspect, and as an article of commerce, E. GROSS (*London: Scott, Greenwood & Co., 1900, pp. 341, figs. 78; transl. from German by C. Salter*).—The history of the hop; the hop plant, its cultivation, preservation, and storage; physical and chemical structure of the hop cone; statistics of production, methods of judging the value of hops, and the hop trade, are considered in a comprehensive manner from the European standpoint.

History of the potato treated from the historical, biological, pathological, cultural, and utilitarian standpoint, E. ROZE (*Histoire de la pomme de terre traitée aux points de vue historique, biologique, pathologique, cultural, et utilitaire. Paris: J. Rothschild, 1898, pp. XII + 464, pl. 1, figs. 158*).—An exhaustive monograph on the potato. Part I discusses the wild potato, giving extended attention to the native home of potatoes and the history of its introduction into England, France, and Continental Europe. Part II takes up the biology, insects and diseases, culture, and use of the potato. The chapter on diseases contains the results of the author's personal observations. The chapter on potato uses discusses potato starch, manufacture of sirup, dextrin, and spirits from potatoes, in addition to the usual uses as food and forage.

Experiments in grafting potatoes, E. LAURENT (*Bul. Roy. Soc. Bot. Belg., 39 (1899), pp. 9, 85; abs. in D'Ing. Agr. Gembloux, 11 (1900), No. 5, p. 213*).—Experiments were made to study the reciprocal influence of grafting light-fleshed and colored varieties of potatoes on each other. The Négresse potato, a variety characterized by deep violet-colored tubers, was grafted on Simson, Boule d'Or, and Blue Giant potatoes, varieties with light-colored tubers. In one series cleftgrafting of the vines was practiced and in another a cylindrical piece 15 mm. in diameter was taken from one tuber and replaced by a piece of similar size from the other. The tests extended over a period of 3 years. The results show that the violet-coloring matter elaborated in the leaves of the Négresse variety was in no instance stored up in tubers of the light-fleshed varieties.

Experiments on the manuring of potatoes in 1899, R. P. WRIGHT (*Bul. West of Scotland Agr. Col. 1900, No. 4, pp. 3-26*).—The data here reported have been in part summarized from another source (see above).

The "other side" of ramie (*Planting Opinion, 5 (1900), No. 48, p. 816*).—A popular note on the practicability of manufacturing fabrics from ramie fiber, showing that existing conditions are not promising.

Sorghum, G. W. SHAW (*Oregon Sta. Rpt. 1900, pp. 21-23*).—Cooperative experiments with a number of varieties of sorghum for sirup making were carried on and the results of analyses of the canes are presented in a table.

Spelt (Triticum spelta), C. A. ZAVITZ (*Farming World, 18 (1901), No. 19, pp. 448, 449*).—Fifteen bushels per acre of grain in the chaff was the best yield obtained by the author in a test of 5 varieties of spelt. The average yield of straw per acre was $\frac{3}{4}$ ton.

Sugar beets in 1897, M. E. JAFFA (*California Sta. Rpt. 1898, pp. 136-142*).—Tabulated results of analyses of sugar beets grown in several counties of the State and at the experiment station and the substations during the season of 1897 are reported. The beets at the stations grown on alkali soils, averaging about 5,000 lbs. of soluble salts to the acre, varied in sugar content from 10.92 per cent in Dumesmay to 18.12 per cent in Vilmorin Améliorée, with a purity coefficient of 71.50 and 90.14, respectively. The average sugar content of all samples was 14.10 per cent. The weight of sample beets varied from 7.5 to 28.3 oz.

Some interesting experiments on sugar-beet culture, L. GRANDEAU (*Jour. Agr. Prat., 1900, II, No. 51, pp. 896, 897*).—A partial book review of a recent work

entitled *Successful sugar-beet culture* (Ertragreicher Zucker-Rübenbau), by F. Kiehl. The book is a résumé of a long series of practical and methodical observations made by the author, who has grown sugar beets for 40 years and who for the last 14 years has given his attention to their culture on a large scale. The subjects considered in the work are rotation, fertilization, methods of cultivation, number of cultivations by hand, distance between plants, time of thinning and harvesting, and varieties. This article treats of the rotations and the application of barnyard and sheep manure.

Beet-sugar industry in Germany in 1899-1900, L. GRANDEAU (*Jour. Agr. Prat.*, 1900, II, No. 52, pp. 933, 934).—This article, based on the exhibits at the Paris Exposition and the publications issued for that occasion, treats of the condition of the beet-sugar industry in Germany at the present day.

Beet roots and their crowns, G. W. SHAW (*Beet Sugar Gaz.*, 2 (1900), No. 11, p. 5).—This article briefly discusses the comparative richness of beet roots and their crowns and gives the results of a study on the subject. The average results of 228 analyses show a difference of 2.09 per cent of sugar in the juice and 6.69 per cent in the purity coefficient in favor of the beet roots as compared with the crowns.

Influence of sugar-beet culture on the yield of grain, J. BÉNARD (*Semaine Agr.*, 20 (1900), No. 1020, pp. 385, 386).—In this article the author gathers data from different countries and shows that sugar-beet culture considerably increases the yield of the grain crops which follow.

The culture of tobacco, MAKHORKA (*Report of the experiment plantation of the Lohkwitz Society of Agriculturists for 1896 and 1897; rev. in Selsk. Khoz. i Lygesov.*, 196 (1900), Feb., pp. 379-439).—An extended series of experiments is described relating to the denseness of planting, the influence of hoeing, irrigation, of different methods of cultivation, of deep plowing, of manure and mineral fertilizers, etc. The experiments are being continued and no final conclusions have been reached as yet.—P. FIREMAN.

Nicotin in California-grown tobaccos, G. E. COLBY (*California Sta. Rpt.* 1898, pp. 149-154).—The author reviews the work of other stations in this line and reports the percentage of nicotin found in the water-free substance of 11 varieties of tobacco grown on the station plats. The nicotin content varied from 2.23 per cent in Vuelta Abajo to 9.03 per cent in Pano de Sumatra. Conqueror Louisiana and Brazilian were the only other varieties with a nicotin content under 5 per cent. From this preliminary work the author concludes that the cigar-leaf varieties give promise of success under California conditions.

Velvet bean and cowpeas (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 12, p. 724).—A brief note comparing the growth of the two plants in Jamaica.

Wheat trials (*New Zealand Dept. Agr. Rpt.* 1900, pp. 316-326, pls. 19).—A report on a test of 40 varieties of wheat grown two years in succession in the North and in the South Island. Each variety is briefly described and representative heads of all but 2 varieties are figured. A tabular statement of the results of the season 1899-1900 is given on page 253 of the same publication.

Wheat, J. S. NEWMAN and J. S. PICKETT (*South Carolina Sta. Bul.* 56, pp. 12).—The results of experiments reported in this bulletin indicate that introduced wheats ripen earlier as they become acclimated to the South, and that the acclimated varieties are to be preferred. One bushel of seed per acre gave the best results as compared with other quantities. Applying nitrate of soda when sowing the seed in the fall gave somewhat better results than its use as a top-dressing in spring. It was assumed that 600 lbs. of cotton seed and 200 lbs. of cotton-seed meal contain equal amounts of plant food, but when applied as fertilizer upon this basis cotton seed yielded an average of 2 bu. per acre more than the meal. Lime applied to the previous crop increased the yield on 5 plats by 1.55 bu. per acre. A plat plowed 6 in. deep yielded 8.4 bu. per acre more than a plat not plowed before sowing.

HORTICULTURE.

Horticultural division, F. W. CARD and G. E. ADAMS (*Rhode Island Sta. Rpt. 1900, pp. 247-267, figs. 5*). -The horticultural work of the year has been along the lines of orchard culture, lettuce forcing, rhubarb growing, and experiments to test the frost resistance of plants and in the crossing and plant selection of strawberries. Some notes on the apple maggot and carnation-stem rot included in the report are noted elsewhere.

The second season's work in lightly fertilizing, cultivating and spraying with Bordeaux mixture and Paris green a neglected orchard (E. S. R., 12, p. 746) has given encouraging results and suggests the feasibility of making profitable by this method many of the neglected orchards of the State.

The frost resistance of three varieties of bush beans has been studied. The beans were grown in the hot bed. After they were well up the sash was removed and the plants exposed to frost on a cold night. Many of the plants were killed outright; others severely hurt, while a few showed little injury. Seed from these was saved and the plants subjected to similar treatment in the spring of 1900. The temperature in the neighborhood on the night of the exposure fell to 28° F. Again, a few plants remained uninjured. It is proposed to continue the work from year to year. Some of the resistant seed sown in the open field in comparison with ordinary seed showed more vigor in resisting cold and untoward conditions and made a stronger growth.

The pot experiments made in 1899 with lettuce to determine the profitableness of substituting commercial fertilizers for stable manure in the production of this crop (E. S. R., 12, p. 746) were carried out on benches in 1900. The soils used were garden loam and a mixture of one-third garden loam and two-thirds hotbed compost with clay added. Commercial fertilizers were added to the garden soil but nothing was used to lighten and improve its physical condition. The result was a complete failure of the crop. On the stable manure plats the plants averaged 115.8 gm. each.

Before planting the second crop the stable manure plat was divided and boneblack and muriate and sulphate of potash applied to one-half. No additional fertilizers were applied to the garden soil but some 2 bu. of sphagnum moss was thoroughly incorporated with it. Again, the crop on the garden soil plat with the commercial fertilizers was practically a failure, while on the stable manure plat the crop averaged 151.2 gm. per plant when commercial fertilizers were added and 150.66 gm. without them. Before planting the third crop an attempt was made to improve the physical condition of the garden plats composed of soil and sphagnum moss by the addition of sand and a

thorough working over. The crop was improved considerably but still fell far behind the stable manure plot.

"It should not be inferred from these experiments that good lettuce can not be grown with chemical fertilizers but the experiments do indicate that it is more difficult to secure the requisite conditions and satisfactory results with chemicals than with stable manure, since the stable manure not only furnished apparently all the food needed for the production of three successful crops but what is probably more important it affords the requisite physical condition of the soil."

A further test of the value of commercial fertilizers was made under practical conditions on good lettuce soil in a commercial lettuce house at Auburn, R. I. A top-dressing of complete commercial fertilizers was compared with a top-dressing of manure. It is reported that "plants grown with top-dressings of chemicals did not start off so well as those receiving a top-dressing of manure but at harvest time they were superior, being decidedly heavier than those grown entirely with manure."

Some notes are given on the relative advantages of heating lettuce houses by means of stable manure and with coal. The latter is believed to be the cheaper method and more fully under the control of the grower.

In experiments in forcing rhubarb in cellars entirely devoid of artificial heat, the conclusion was reached that a warm cellar or one in which a little artificial heat is supplied is needed to produce rhubarb sufficiently early to make the practice desirable.

A record was kept during the season of the character and behavior of the plants in the strawberry field. A portion of the data are recorded. A remarkable variation in the yield of individual plants of the same variety occurred. With Beverly the highest yield per plant in grams was 285.8 and the lowest 34.5. Similar variations occurred with many other varieties. Usually plants giving the highest yields produced fruit equal to and in many cases above the average. The detailed yields of plants of 8 varieties chosen to be used in future plant selection experiments are shown in tabular form and the more successful crosses secured are noted.

Report on the substations, C. H. SHINN (*California Sta. Rpt. 1898, pp. 262-327, figs. 19*).—This report includes data on meteorology and the farm and orchard crops grown at the Foothill, Southern Coast Range, San Joaquin Valley, and Southern California culture substations. The fruits tested include apples, pears, almonds, apricots, nectarines, peaches, cherries, plums and prunes, figs, olives, walnuts, oranges and lemons, persimmons, quinces, mulberries, date palms, dwarf and ornamental apples, and grapes. The farm crops grown were barley, wheat, saltbushes, grasses, clovers, and other forage plants, cotton, soy beans, cañagre, etc.

In investigating the moisture content of hardpan soils at the Southern Coast Range Substation it was found that the uncultivated soil contained 2.6 per cent moisture, while cultivated orchard soil contained 3.3 per cent moisture. With the same rainfall, cultivated adobe soils (not hardpan) contained 12.3 to 16.1 per cent of moisture. Trees on the adobe soil made a growth of from 20 to 26 in., while those on the hardpan soils made growths of from 4 to 10 in.

A number of illustrations, with some data, are given, showing the value of gypsum in the reclamation of alkali lands at the San Joaquin Valley Substation.

At the Southern California Culture Substation a test was made of canning peaches. Six boxes of Yellow Tuscany Cling, California Cling, McDevitt Cling, Runyon Orange Cling, Sellers Cling, and Nichol Orange Cling were assorted and sent to a cannery and put through the process with the regular pack of other fruits supplied by local growers. At the end of the season the cans were opened and the fruit examined with reference to the appearance of the fruit as to color, absence of red at the pit, firmness of flesh, and clearness of juice. The results, as determined by the best local experts, were as follows:

"Sellers Cling and Yellow Tuscany stood first in firmness, absence of red at the pit, and color. Yellow Tuscany stood first in clearness of juice. . . . McDevitt Cling stood second in this respect, and the other clings were considered decidedly inferior to the above as canning peaches, not only in quality, but in firmness and appearance. California Cling had the greatest number of split pits; Nichol Cling and McDevitt came next in this regard. Sellers Cling was entirely and Yellow Tuscany was practically free from split pits."

Yellow Tuscany is considered a very productive variety. Lovell is regarded as the most promising of the yellow freestones for canning or drying.

Some experiments with self-pollenized olives were carried on at this station. Blossoms tied in paper bags failed to produce any fruit except in one or two cases, with medium sized olives. On a larger scale in the station orchard the value of mixing varieties was apparent.

As yet cotton has not proved a paying crop in southern California, where land and labor are so high priced.

California apples, G. E. COLBY (*California Sta. Rpt. 1898, pp. 143-148*).—Physical, food, and ash analyses are given of 7 varieties of apples grown in different parts of the State. The largest apples and the ones richest in juice, sugar, and acid were grown in the high foothills and mountain localities. The percentage of sugar in whole fruit averaged 11.62, as compared with 8 to 9 per cent in eastern grown and European apples. So far as examined, the apple seems to withdraw much less mineral matter from the soil than any of the other orchard fruits (except pears), averaging only 0.264 per cent of ash in the whole fruit. The ash averaged over $\frac{1}{2}$ potash and $\frac{1}{3}$ phosphoric acid.

The following table shows the fertilizer ingredients contained in 1,000 lbs. of a number of California fruits and nuts:

Soil ingredients contained in 1,000 pounds of fresh fruit.

Fresh fruit (crop of 1,000 lbs.).	Total ash.	Potash.	Lime.	Phosphoric acid.	Nitrogen.
	Pounds.	Pounds.	Pounds.	Pounds.	Pounds.
Almonds	17.29	9.95	1.04	2.04	7.01
Apricots	5.08	3.01	.16	.66	1.94
Apples	2.64	1.40	.11	.33	1.05
Bananas	10.78	6.80	.10	.17	.97
Cherries	4.82	2.77	.20	.72	2.29
Chestnuts ^a	9.52	3.67	1.20	1.58	6.40
Figs	7.81	4.69	.85	.86	2.38
Grapes	5.00	2.55	.25	.11	1.26
Lemons	5.26	2.54	1.55	.58	1.51
Olives	13.50	9.11	2.43	1.25	5.60
Oranges	4.32	2.11	.97	.53	1.83
Peaches	5.30	3.94	.14	.85	1.20

Walnuts ^a	12.98	8.18	1.56	1.47	5.41

^a Including hulls.

"The figures found for apples (and pears) are, on the whole, so much smaller than those which have been obtained for the other ordinary orchard fruits that it would seem safe to conclude that here fertilizers will not be necessary for apple crops for many years to come. However, the figures do indicate that the first need will be for a nitrogenous fertilizer, and this is about what this station has been led to recommend for most of our fruits. Along with this need will also come that for a phosphatic fertilizer. There is no reason to supply potash to apple orchards for a great many years to come. The rather high quantity of sulphuric acid in the ash of apples, like that of the ash of cherries and oranges, indicates the occasional need of a dressing of gypsum to the soil, which not only supplies the necessary sulphuric acid, but helps to make the potash present more available."

The condition of success with grafts, L. DANIEL (*Rev. Gén. Bot.*, 12 (1900), Nos. 141, pp. 355-368; 142, pp. 405-415; 143, pp. 447-455; 144, pp. 511-529).—The author reviews the earlier beliefs respecting conditions necessary for the successful grafting of plants on each other, defines certain terms used in grafting, and gives the conditions necessary for success in grafting a large number of plants belonging to different species, genera, and families.

Grafts are divided into two groups—grafts by approach, or anatomical grafts, and true or physiological grafts. The graft properly called, or physiological graft, is divided into two classes—ordinary grafts and mixed grafts. There is an ordinary graft proper when the stock is deprived entirely of its assimilating apparatus and the scion of its absorbing apparatus. In the mixed graft proper the stock may preserve part or all of its assimilating apparatus, and the scion part or all of its absorbing apparatus. In grafting by approach success is considered to be attained when the two plants grow together in an enduring manner, so that if separated a wound is formed. The graft proper is said to succeed when after having lived a certain length of time on the stock the scion fructifies and produces fertile seeds.

The conditions of success of grafts are divided into two groups, extrinsic conditions, *i. e.*, conditions independent of the nature of the plant, as soil, temperature, etc., and intrinsic conditions, or conditions dependent upon the peculiar nature of the plants grafted, as method of cicatrization, analogy, and botanical relations. The extrinsic conditions which it is necessary to observe in grafting by approach are summarized as follows: (1) A temperature sufficient for the production of the meristem, (2) the prevention of all conditions which cause rotting or drying of the cicatrizing meristem, and (3) maintenance of adherence of the wounds by the aid of ligatures susceptible of being loosened progressively with the growth of the plant.

Under intrinsic conditions in grafting by approach cicatrization is first considered. Plants cicatrize their wounds either by simple drying of the cut tissues and neighboring cells or by regeneration of tissues by the aid of the meristem. The author thinks it may be possible to graft plants by approach which cicatrize the wound by drying up, but this could be accomplished only by compression when operating with very young tissue in a way to produce an artificial concrescence. This last method has not been tried, but all methods by cutting have failed in the divers monocotyledons and the majority of the cryptogams. Thus the author has not been able to graft *Ruscus*, ferns, bamboos, or maize, and hence formulates the fourth fundamental condition of success in grafting by approach as follows: Grafting by approach is impossible with all plants which cicatrize their wounds by desiccation of the wounded cells and neighboring tissues—that is to say, are incapable of regenerating their tissue.

In order to learn whether only plants possessing cambium tissue are able to be grafted, as generally held, the author operated on a number of monocotyledons and cryptogams. A perfect cicatrization of the wound was obtained by the tongue graft with *Gladiolus*, *Funkia cordata*, day lily, *Philodendron*, caladium, white lily, *Globba coccinea*, etc., but the most interesting result was the success of the cicatrization of *Selaginella arborea*. The success of these grafts shows that grafting by approach is possible with certain monocotyledons, and that the presence of the cambium layer is not always necessary to the success of all grafts by approach.

Under analogy in grafting by approach, plants essentially different in wood and bark structure are first considered. Borecole and turnip, the structure of which is very different, were easily grafted, forming a perfect suture between the ligneous layer of the borecole and the medullary parenchyma of the turnip. The difference in the hardness of woods and their histological nature may not be an obstacle to anatomical union. A natural, distinct cicatrization occurred between the grafted oak and the beech and between the fir and linden; the oak and the ash united by their stems, and the oak and the walnut united

by their roots. The rose and the grape have also been united. Nevertheless, the graft by approach does not always succeed between plants so different. Thus the author endeavored in vain to graft the horse-chestnut and the common chestnut.

The author considers analogy in cell contents as affecting the graft by approach, and it is shown that the accumulation of reserve material in different vegetative parts of plants has no special importance in grafting, as is proved by the success attained in grafting by approach the turnip and cabbage, borecole and kohlrabi, Brussels sprouts and kohlrabi, and kohlrabi and cauliflower. Even grafting by approach between roots of lettuce and aged salsify succeeds, though the inulin of the salsify roots is not able to circulate in the cell membrane of the lettuce. But if the cell contents of one of the plants approached are toxic for the other, the graft fails. Thus the author was not able to graft celandine and salsify, salsify and burdock, etc.

Under analogy in method of development, it is shown that if a large and a small variety are grafted on each other, the larger variety will develop to the detriment of the smaller, which will remain nearly dwarf. Plants of different forms, like borecole and cauliflower, may make good unions. Plants in active condition of growth may be grafted by approach on plants at rest. Thus a seedling cabbage several weeks old was grafted in the spring time on a turnip, the root of which was already completely formed. The graft succeeded perfectly. The graft by approach succeeds between annuals, biennials, and perennials. Thus peas, sweet peas, and toad flax have been united. The symbiosis ceased at the death of the annual species. The same fact was observed in grafting by approach biennial and perennial plants. The success of the graft between the fir and the linden, and *Aralia spinosa* and *A. sieboldii*, shows that deciduous and evergreen plants may be grafted on each other.

With the graft proper, as with the graft by approach, all of the extrinsic conditions, such as temperature, rotting and drying of the meristem, and necessity of contact of the wounds, are present, but in cutting off the top of the stock and suppressing the absorbing apparatus of the scion there is danger of the death of both plants. Another fundamental extrinsic condition of success, then, must be the maintenance of the life of the two plants until success is complete. The scion is sometimes preserved by placing it in water as soon as it has been prepared. This prevents it from drying out, keeps the cut surface clean, and prevents the formation of sugar or other materials on the cut ends which might interfere with the free passage of sap from stock to scion, and is recommended.

In order that the scion may be able to grow, it is necessary to reestablish the turgescence of its tissues. This reestablishment is made by imbibition of the crude sap of the stock by the cells of the scion. The

reestablishment of turgescence is effected more quickly according as the crude sap is presented in considerable quantity, but also more quickly if the initial turgescence of the tissues of the scion has not been diminished during the preparation of the graft and its putting in place. This explains why it is necessary to operate quickly and why the cutting of the graft under water, where the scion preserves in a large part its turgescence, produces such good results. It also accounts for the good effects of the waxlike material in grafting in the open air; the utility of the collar graft, because the osmotic force is strongest at this level; and the importance of the time of day in operating, because the osmotic force varies in the course of the day, being strongest in the evening (hence the greater success of grafting in the evening). The reestablishment of the turgescence in the graft is cited as a fundamental condition of success, therefore it is not possible to graft parts of plants which are incapable of retaking their turgescence or which do not possess it entirely.

Under intrinsic conditions, it is shown that in the graft proper, as in the graft by approach, plants incapable of regenerating their tissues can not be grafted. The author succeeded in grafting by the graft proper the white lily, *Gladiolus*, *Funkia cordata*, etc., when operating on young stems. In all these grafts the anatomical cicatrization was effected by the parenchymatic tissues. No liber or fibrovascular structure was observed to form between scion and stock. The transport of the sap was thus singularly hindered, and at the end of a variable period one of the parts, or both, died. By utilizing the aerial roots, which some of the monocotyledons possess, to supplement the absorption of the scion, success was attained with a number of plants. This shows that the nonsuccess of the graft with monocotyledons capable of regenerating their tissues comes from insufficient vascular communication, since it becomes possible when a complementary absorption apparatus is supplied.

Plants with active cambium layers, which may be grafted by approach, can not always be grafted by the graft proper, since the common European bean (*Faba vulgaris*) and the kidney bean, which graft easily by approach, have always failed when grafted by the graft proper, no matter what precautions were taken.

Differences in wood and bark are not obstacles to success in the graft proper. Thus there is a great difference in the thickness and strength of the safflower and the annual sunflower; between the sunflower and the Jerusalem artichoke; the young cabbage and the root of the turnip; the root of the cultivated carrot and that of fennel; nevertheless, these plants united perfectly. These same facts were observed with trees, the graft succeeded between the chestnut and the oak, the pear and the hawthorn, the hawthorn and the quince, in spite of the marked differences in the barks. From these and other grafts, it is concluded

that hardness, density, and elasticity of wood play a secondary rôle in the success and duration of grafts, but it is not the same with conduction. When the differences of sap conductions are too great the grafts will not succeed. As an example may be mentioned the grafts between the lilac and ash, cherry and almond, cotoneaster and chestnut, etc., which grow the first year, then die without fructifying. The duration of the graft is then very variable and depends for its value on the differences in conduction between the scion and the stock. Thus the pear grafted on the quince endures for a shorter period than the pear grafted on the pear seedling. When the differences of conduction are too great between two plants, the mixed graft is sometimes used successfully where the ordinary graft fails. By the use of the mixed graft the author was able to unite *Vernonia praelata* and *Xanthium macrocarpum*, which failed by the ordinary process of grafting.

The author has succeeded in grafting plants whose cell contents presented very marked differences. Thus the grafts of *Chicoriaceæ* and of divers *Euphorbiaceæ*, etc., show that plants with different latex contents succeed, although it has been previously held that plants with a milky juice could not be grafted.

A number of grafts were made to determine what influence reserve material in plants might have on grafting. The easy grafts on roots of the carrot and parsnip show that the presence of reserve material is no obstacle to success. The graft of the tomato on the potato, annual sunflower on the Jerusalem artichoke, etc., show that the formation of tubers on the stock takes place even when the scion is incapable of producing tubers itself. In grafting in September a young cabbage on the purple-topped turnip, which would have commenced to form its tuber in October, the turnip tuber formed only the month of April following, when the scion became plethoric. It is then the scion which by its mode of nutrition commands the function of reserve material in the stock.

The inverse graft of plants susceptible of forming tubers on a plant which does not yield tubers may be realized. Thus the author succeeded in grafting *Helianthus luteiflorus*, species with enlarged rhizome, on *H. annuus*, an annual species not forming tubers. The scion grown entirely above the soil was unable to form tubers. The reserves which were formed passed into another form in the stock, which took a development altogether abnormal and became very ligneous. The potato grafted on eggplant and tomatoes has been observed to form aerial tubers and thus store up its reserve material.

Analogy in habitat seems to be a more or less important factor. Thus *Phlox decussata*, which grows in humid soils, has not been successfully grafted by the author with *P. subulata*, which grows on dry soils; though parsley, which prefers a dry soil, succeeds when grafted with *Sison ammonium*, which prefers a humid soil. In the case of trees,

pears are grafted on quince in rich soil and on pear seedlings in poor soil, etc. Different soils then are not the most serious obstacles to success in grafting, but they seem to have more or less marked influence on the duration of the graft.

If a dormant ligneous scion is grafted on an active ligneous stock, success follows, but does not follow if conditions are reversed. With herbaceous plants, an active scion may be grafted on a dormant stock and succeed. When the scion and stock do not come into activity about the same time, the graft may succeed, but the duration of the graft will be shortened.

In order to study the limits of the possibility of grafting, experiments were made with the following families of plants: Rosaceæ, Umbelliferæ, Leguminosæ, Cruciferæ, Solanaceæ, and Compositæ. With Rosaceæ, Leguminosæ, and Cruciferæ, the limit of grafting seems to be confined to genera of the same tribe. With Solanaceæ and Umbelliferæ, grafts were successfully made between different tribes. With Compositæ the limit of grafting seems to be the subfamily.

Horticulture from an educational standpoint, F. W. CARD (*Rhode Island Sta. Rpt. 1900*, pp. 268-276).—A popular essay on this subject.

The principles of vegetable gardening, L. H. BAILEY (*New York: Macmillan Co., 1901, The Rural Science Series*, pp. 458, figs. 114).—A popular, comprehensive treatise on various phases of gardening operations and the culture of all the more usual vegetables. Part I contains chapters on the lay-out of the plantation, use of glass, the soil and its treatment, vegetable gardening tools, seeds and seedage, subsequent management of the vegetable garden, marketing, and storing. Part II discusses vegetable gardening crops. These are classified into root, tuber, bulb, cole, pot herb, salad, pulse, solanaceous and cucurbitous crops, sweet corn, okra, martynia, condimental and sweet herbs, and perennial crops. The work also contains a bibliography of over 100 American works on vegetable gardening. Not the least valuable features of the work are extensive illustrations of gardening tools and of seedling plants of all the more common vegetables.

Greenhouse production of market garden crops, W. W. RAWSON (*New Jersey State Bd. Agr. Rpt. 1899*, pp. 179-196).—Brief notes on greenhouse construction and on the forcing of asparagus, beets, beans, cauliflowers, cucumbers, dandelions, lettuce, parsley, rhubarb, and radishes.

Asparagus culture, J. J. T. NORFOLK (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. 4, pp. 646-652).—Popular directions for growing lettuce in the field, garden, and greenhouse in England.

Keeping quality of Prizetaker onion (*Amer. Gard. 22* (1901), No. 319, p. 76).—In the experience of the author the keeping quality of this onion has been made equal to that of any other variety by the liberal use of available potash.

Fertilizer test with sweet potatoes, B. W. KILGORE, R. W. POE, and A. H. PRINCE (*Bul. North Carolina State Bd. Agr.*, 21 (1900), No. 11, pp. 38-42, figs. 2).—Report of an inconclusive test of various fertilizer elements and combinations for sweet potatoes. Yellow Nansemond and Bunch Yam were the best varieties grown.

Edible and poisonous mushrooms and toadstools, W. TRELEASE (*Missouri State Hort. Soc. Rpt. 1900*, pp. 224-241).—Besides general notes and descriptions, a bibliography of 48 papers is given.

Preservation of beans in brine, ZSCHOKKE (*Jahresber. Vers. Stat. u. Schule, Wädenswil*, 1897-98, pp. 41, 42).—In an experiment in the preservation of string

beans in brine 10 kg. of green beans (seeds and pods) were put in one crock, 10 kg. of slightly steamed beans in another, and 10 kg. of beans steamed until they were soft, in a third. In each case the beans were stringed. The crocks were lined with full-grown grape leaves, and the beans covered with the same and with cheese cloth. Each crock was salted alike, 50 gm. of salt being used for each kilogram of beans. The beans were kept under brine by means of a weighted cover. After 4 to 4½ months, the crocks were opened. In each crock the beans were of a good green color and the quality equally good. The pods were slightly tougher where they had been salted without steaming. The author believes that in keeping beans in brine most satisfactory results are obtained if the beans are first steamed, quickly cooled off, and then salted in the crocks cold. When beans are salted without steaming, only the young pods should be taken.

First annual report of the board of trustees of the Missouri Fruit Experiment Station (*Rpt. Bd. Trustees Missouri Fruit Expt. Sta. 1900, pp. 20*).—Report of progress on buildings and orchard setting, with a financial account for the year. Bitter rot and apple scab were largely controlled by spraying with Bordeaux mixture.

Fertilizing peaches and other crops, B. TYSON (*Amer. Gard., 22 (1901), No. 319, p. 76*).—Suggestions as to methods and amounts of fertilizers to use for peaches and wheat.

Japanese plums, G. S. BUTLER (*Trans. Massachusetts Hort. Soc. 1900, pt. 1, pp. 102-110*).—Cultural suggestions, with descriptions of a few varieties and notes on synonyms.

Japan plums, H. O. MEAD (*Rural New Yorker, 60 (1901), No. 2664, p. 103*).—The essential principles of culture are given in condensed form and represent the experience of the author for 15 years. A high, fairly dry location, and one-year trees 4 to 5 ft. high budded on peach stock, and planted 13 to 16 ft. apart are recommended. Early potatoes and berries can be grown in the orchard the first year or so without harm, after which the orchard should be cultivated and a humus crop grown each year to turn under. The plums must be thinned. Fertilizers with not too much nitrogen, a fair amount of phosphoric acid, and plenty of potash are advised.

Information on coffee in Costa Rica (*Estudio é informe sobre el café de Costa Rico. San José: Government, 1900, pp. 48*).—Of a commercial nature and containing analyses of several samples of coffee.

American vines for the reconstruction of French vineyards; description of the principal varieties of stocks and direct producers, J. GRANDVOINET (*Les cépages américains pour la reconstitution du vignoble français; description des variétés principales porte greffes et producteurs directs. Paris: Octave Doin, 1900, pp. 108, figs. 47*).—Nearly 50 species and varieties of American grapes are described. Natural size illustrations of the leaves of the different varieties are given, and the adaptability of the vines to different soils and their resistance to the phylloxera are noted.

Tests of chemical fertilizers on grapes in 1900, E. CHUARD and C. DUSSERRE (*Chron. Agr. Canton Vaud, 14 (1901), No. 2, pp. 29-38*).—This is an account of cooperative experiments carried out by the viticultural station of the Canton of Vaud to test the desirability of substituting commercial fertilizers for half the barnyard manure usually employed in fertilizing grapes. The results show the practice to be economical and desirable.

Making a cranberry bog (*Rural New Yorker, 59 (1900), No. 2656, p. 847*).—Notes on methods of preparing and utilizing swamps and details of planting and harvesting the crop.

Chestnut farming in Pennsylvania (*Rural New Yorker, 60 (1901), No. 2663, p. 82*).—An account of a weevil-free orchard grafted on chestnut stump saplings with selected wild chestnuts. The orchard is located high up on the mountains. The selected nuts are very large—nearly, if not quite, as large as Paragon nuts—and the quality is equal to small native sweet varieties.

India rubber, gutta-percha, and balata, W. T. BRANNT (*Philadelphia: Henry Carey Baird & Co., 1900, pp. XXIV + 328, figs. 24*).—Discussion of the "occurrence, geographical distribution, and cultivation of rubber plants; manner of obtaining and preparing the raw materials; mode of working and utilizing them, including washing, loss in washing, maceration, mixing; vulcanizing rubber and gutta-percha compounds and utilization of waste; balata and statistics of commerce."

The caoutchouc plants and their culture, O. WARBURG (*Die Kautschukpflanzen und ihre Kultur. Berlin: Kolonial-wirtschaftliches Komitee, 1900, pp. 154, figs. 111*).—This work purposes to sum up and critically examine the many detailed observations on caoutchouc plants, the object being to give a true idea of these plants, their culture, etc. The first chapter treats of caoutchouc production and consumption, thus giving a general idea of the commercial importance of the subject in different countries.

Gums, resins of exotic origin, and vegetables which produce them, particularly in the French colonies, H. J. DE CORDEMOY (*Gommes, résines, d'origine exotique, et végétaux qui les produisent, particulièrement dans les colonies françaises. Paris: Augustin Challamel, 1900, pp. 312, figs. 47*).—The work is divided into 3 parts. Part 1 defines, gives the general properties, and describes a large number of gums and the trees producing them. In the same manner, part 2 treats of resins and part 3 of resin-gums.

The cultivation of medicinal plants (*Amer. Gard., 22 (1901), No. 319, pp. 73, 74*).—Summarized suggestions of H. H. Rusby, College of Pharmacy, New York City, regarding the probable profits in growing a number of medicinal plants.

The improvement of the carnation in America, C. W. WARD (*Trans. Massachusetts Hort. Soc. 1900, pt. 1, pp. 91-101, pls. 6*).—Historical notes, brief description of the process of hybridizing carnations, descriptions of a number of prominent American varieties with illustrations, and some statistics concerning the magnitude of the carnation industry in the United States.

Groff's hybrid gladioli, M. CRAWFORD (*Amer. Gard., 22 (1901), No. 322, pp. 131, 132*).—The requirements of a standard gladiolus are set forth and Groff Hybrid shown to compare favorably with it.

Rose growing under glass, T. PRICE (*Amer. Gard., 22 (1901), No. 321, pp. 111, 112, fig. 1*).—Popular directions for soil, planting, watering, ventilation, supports, propagation, and varieties, with notes on insects and diseases of roses.

On the cross-fertilization or hybridization of roses, S. MOTTET (*Rev. Hort., 73 (1901), No. 3, pp. 67, 68; transl. in Amer. Gard., 22 (1901), No. 327, pp. 227, 228*).—Details of methods.

Water lily pond, G. ABBEY (*Jour. Hort., 53 (1901), No. 2729, pp. 49-51, figs. 2*).—An illustrated outline plan with lists of suitable plants.

Distribution of seeds, plants, cuttings, etc., E. J. WICKSON (*California Sta. Rpt. 1898, pp. 233-236*).—Summarized statement of the amount and kinds of seed distributed by the central experiment station since 1886, with financial statement regarding the same for the 6 years ended 1899.

FORESTRY.

Report of the forestry substations, C. H. SHINN (*California Sta. Rpt. 1898, pp. 328-351, figs. 7*).—A report is given of the history and present condition of the forestry substations located at Chico and Santa Monica. The Chico forestry station was originally a part of the Chico ranch, which formerly belonged to General John Bidwell. The previous owner began collecting the native and finer exotic trees as early as 1856, and notes are given on the present growth of a num-

ber of the finer specimens. Numerous specimens of *Pinus sabiniana* and *P. ponderosa* are now more than 100 feet in height, with trunks from 8 to 11 feet in circumference. Specimens of *Sequoia gigantea* and *S. sempervirens* are from 80 to 90 ft. in height and from 4 to 5½ feet in circumference. A native cottonwood planted in 1856, at the time of this report was 100 ft. high and the circumference of the trunk was 16 ft. Notes are given on the present size of a number of other species. The climatic conditions shown by records kept at the station since 1885 are given, together with notes on the more recent additions to the arboretum. Statistics are given on the rate of tree development in which are shown the rate of growth of a large number of coniferous and deciduous trees. Experiments have been conducted on the planting of various oaks, principally the English oak (*Quercus pedunculata*). The results obtained seem to indicate that in the central Sacramento Valley the planting of oaks for timber might prove profitable. Next to the oaks, different varieties of ash promise the best results as hard wood forest trees. An account is given of the willow collection at the Chico Station, in which the characteristics and rate of growth of the 15 best species are shown. Descriptive notes are also given on a number of species of Eucalyptus and Acacia at the Chico Station.

Among the more interesting statements regarding the Santa Monica Station are the notes showing the effect of drought on different trees. The deficient rainfall for two successive years served to indicate the more hardy species of trees adapted to that region. A list is given of 60 species of the Eucalyptus in cultivation at the Santa Monica Substation in 1899. Illustrative and descriptive notes are given on a few species of Eucalyptus, Acacia, and other trees.

Forest reserves, H. GANNETT (*Twentieth Ann. Rpt. U. S. Geol. Survey, 1898-99, pt. 5, pp. 498, pls. 159, figs. 2*).—This report contains a review of the forests of the United States, by the author, together with detailed reports on some of the forest reserves in the western United States. Descriptions are given of Pikes Peak, Plum Creek, and South Platte reserves, by J. G. Jack; the White River Plateau and Battlement Mesa reserves, by G. B. Sudworth; the Flathead Forest Reserve, by H. B. Ayers; and the Bitterroot, San Gabriel, San Bernardino, and San Jacinto reserves, by J. B. Leiberger. During the year covered by this report 11,000 square miles were added to the forest reserves, the present area devoted to that purpose being 72,139 square miles. This area is composed mostly of mountainous, rugged country, of little or no value for agriculture, but especially favorable to tree growth. Abstracts are given of the reports on different forest reserves, in which the area, the general condition, and permanent species of trees are described. The relationship of forest fires and grazing to forest problems is discussed by the different authors at some length.

The forest nursery, G. B. SUDWORTH (*U. S. Dept. Agr., Division of Forestry Bul. 29, pp. 63, pls. 5, figs. 11*).—The purpose of this bulletin is to inform farmers and others interested in tree planting how to procure forest tree seeds, and raise seedlings at a small cost. The principal point kept in view is to direct the propagator to produce vigorous plants which will succeed best under inexperienced management. The desirability of cooperation among the farmers of a locality is pointed out as a means by which larger privileges of seed and plant exchange are possible. Notes are given on collecting tree seeds and their care before planting. Suggestions are given of when and how to collect the seeds, and methods for storing, and for testing their vitality. Directions are given for the propagation of trees of various kinds from seeds and cuttings, and means to be adopted in wintering and transplanting seedlings. As cheap sources of supply the author recommends the use, so far as possible, of wild seedlings. The bulletin concludes with lists of useful timber trees for planting, in which notes are given of their range, the appearance and character of their fruits and seeds, the time to collect and use them, and methods of storage.

The Minnesota forestry plan, J. N. CROSS (*Forester, 6 (1900), No. 11, pp. 263-266, pls. 2*).—The efforts on the part of various societies and boards to secure forest legislation are briefly reviewed. By means of an educational system in which the newspapers were interested in the project, a sentiment was aroused which finally resulted in the passing of needed legislation.

Under the law creating the State Board of Forestry, it is provided that any person having denuded or other lands worthless for agricultural purposes may deed them to the State, and, upon acceptance, the State undertakes to protect these lands from fires, exempt them for taxation, and, to a certain extent, reseed them so as to render them useful and profitable. Any income realized from these forests is divided into three parts and distributed as follows: One-third is retained to reimburse the State for fire protection, etc.; one-third goes to the educational system of the State; and the remainder to the donor, his heirs, or to whomsoever he may designate.

Under the terms of this law a number of persons have tendered lands to the board and a start has been made. Four years have elapsed since the plan was begun and beneficial results are believed to have been secured.

The forests of Saxony (*Indian Forester, 26 (1900), No. 9, app. pp. 1-15*).—The forest area of the Kingdom of Saxony is said to represent 27.4 per cent of the total area. This is divided into State, communal, and private forests. Descriptions are given of the State forests in which for the 5 years ended in 1891 the revenue amounted to 45.5 marks per hectare. There are in Saxony 108 forest ranges, averaging 1,620 hectares each. The working plans for a number of these ranges

are given. A number of the more important forest districts are described in some detail. The prevailing species in these forests are spruce, followed by beech and fir. The Crottendorf range, which is said to be remarkable for the large profit it yields, is described at considerable length. The net revenue from these forests for the past 10 years has been 121.9 marks per hectare, which represents 4.35 per cent of the estimated value of the range. In some of the forests considerable damage has been done to young spruce trees by the fungus *Trametes radiciperda*.

Forests in the Grand Duchy of Baden (*Indian Forester*, 26 (1900), No. 9, app. pp. 125, figs. 14).—The forests of the Grand Duchy of Baden are said to occupy a total of 36.2 per cent, as compared with an average of 26 for the whole of Germany. This area is divided into State forests, 95,000 hectares; forests belonging to towns, villages, and other public corporations, 270,000 hectares; and private forests, 180,000 hectares. Of these forests, the beech occupies 26.4 per cent of the total forest area; oak 11.1 per cent; other broad-leaved species 14.1 per cent; while spruce occupies 20.8 per cent; silver fir and Scotch pine each 13.6 per cent; and other conifers 0.4 per cent. The methods of treatment followed within the Grand Duchy are described and grouped under the heading of high forest and coppice. The methods of administration are described and working plans for a number of State forests are given. The method pursued in charcoal burning is described at considerable length.

The protection of shade trees in towns and cities (*Connecticut State Sta. Bul.* 131, pp. 30, pls. 9).—This bulletin is the report of a committee appointed by the mayor of the City of New Haven, Conn., to investigate the subject of the protection of shade trees. The present condition of the street trees was indicated and various causes of the destruction of trees were mentioned. Suggestions are given for protecting shade trees against these injuries, and the duties of the city forester are outlined. The necessity for a nursery to provide shade trees for those which have been destroyed from various causes is shown, and descriptions given of the varieties of trees most suitable for street planting.

Concerning a severe injury to street trees through the escaping of illuminating gas, C. WEHMER (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 5, pp. 267-269, pl. 1).—An account is given of the severe injury to a number of trees of *Ulmus campestris*. The injury was caused by a break in a gas main, and it was communicated to the trees through their roots. The bark fell off, the trunks of the trees showing the injury early in the spring, while the buds and twigs appeared in normal condition.

Some unrecognized forms of native trees, S. COULTER (*Proc. Indiana Acad. Sci.* 1899, pp. 112-116).—Brief descriptions are given of a number of well-marked forms of native trees which the author thinks possibly worthy of varietal rank. Among those described are two forms of the papaw which are said to be easily distinguishable. One has a large fruit, which becomes a rich yellow upon ripening; the other has a small fruit, becoming white when ripe. The leaf characters are also different. Three easily distinguishable forms of black walnut are also described, and forms of the common tulip tree and persimmon are also said to exist, in which marked characters may be noted.

Larch culture, F. BAUDISCH (*Oesterr. Forst u. Jagd Ztg.*, 18 (1900), No. 35, pp. 275, 276).—Directions are given for raising larches and their principal insect and fungus enemies are described. Among the latter, *Peziza willkommii*, *Sphaerella laricina*, and *Alloescheria laricis* are said to be the most troublesome, especially to the young seedlings. Suggestions are offered for combating them.

The larch and its culture in Middle and Northern Germany, F. BODEN (*Die Larche ihr leichter und sicherer Anbau in Mittel- und Norddeutschland*. Leipzig: T. Fuenflling, 1900, pp. 140, pls. 3; abs. in *Ztschr. Forst u. Jagdw.*, 32 (1900), No. 10, pp. 636-638).—Some of the problems of larch growing are discussed and especial attention given to the diseases and insects to which it is subject. *Peziza willkommii* is said to be the most serious enemy to its successful propagation.

The white pine in North America, SCHWAPPACH (*Ztschr. Forst u. Jagdw.*, 32 (1900), No. 10, pp. 599-604).—A review is given of Bulletin 22 of the Division of Forestry of this Department (E. S. R., 11, p. 746).

Pinus cembra and its cultivation, A. WODITSCHKA (*Oesterr. Forst u. Jagd Ztg.*, 18 (1900, No 21, pp. 163-166, figs. 11).—Describes the distribution and uses of this pine and gives suggestions for its culture.

Transplanting of large oaks, HINDERLICH (*Gard. Chron.*, 3. ser., 28 (1900), No. 716, p. 203, fig. 1).—An account is given of the successful transplanting of 87 oak trees ranging in size from 19 to 34 ft. in height.

Physiological differences between the sessile and pedunculate oaks, W. R. FISHER (*Gard. Chron.*, 3. ser., 28 (1900), No. 717, pp. 218-220, figs. 2).—Differences between *Quercus sessiliflora* and *Q. pedunculata* are noted. These two species were formerly considered by English botanists as forms of *Q. robur*. *Q. sessiliflora* delights in dry, well drained soil, while the other grows best in moist soils. Differences are noted for the foliage, flowers, and timber. The fact that numerous hybrids between the two species are common is given as the reason for believing they both belonged to the same species.

Observations and experiments at the Krapiva forestry school during the academic year 1898-99, V. KLUCHNIKOV (*Selsk. Khoz. i Lyesov.*, 197 (1900), Apr., pp. 207-224).—During the reported year experiments in storing acorns by various methods were made. It is stated that the fungus *Polyporus sulphureus* attacked the oak, a very rare phenomena.—P. FIREMAN.

The green alder and forest protection, A. MATHEY (*Rev. Eaux et Forêts*, 3. ser., 4 (1900), No. 12, pp. 353-359).—The value of this coppice wood as protective against landslides and avalanches is shown. Its rapid growth is described and it is said to be a good nurse crop for spruce.

Practical forestry in the Adirondacks, B. E. FERNOW (*Tradesman*, 44 (1901), No. 9, pp. 112, 113).—An account of the work of the Cornell School of Forestry, etc.

Notes on some timber trees of the Burnett District of Queensland, V. J. W. FAWCETT (*Queensland Agr. Jour.*, 7 (1900), No. 3, pp. 271-274).—Brief descriptive and economic notes are given on 28 species of timber trees.

The trees of Java, VI, S. H. KOORDERS and T. VALETON (*Meded. 'S Lands Plantentuin*, 1900, No. 40, pp. 1-193).—Descriptions and economic notes are given on the trees of Java belonging to the orders Bixaceæ, Lecythidaceæ, Myrsinaceæ, and Myrtaceæ.

The development of forestry in Japan, H. MATZUNO (*Ztschr. Forst u. Jagdw.*, 32 (1900), No. 7, pp. 406-412).—Traces the development of forestry and establishment of forest control under the government.

The value of commercial fertilizers in reforestation, A. FELBER (*Deut. Landw. Presse*, 27 (1900), No. 98, pp. 1172, 1173, figs. 4).

Forestry at the Paris Exposition of 1900, J. S. GAMBLE (*Indian Forester*, 27 (1901), No. 1, pp. 1-24).—Brief notes are given descriptive of the forestry exhibits and display at the Paris Exposition of 1900.

SEEDS—WEEDS.

Clover seeds and their impurities, F. H. HILLMAN (*Nevada Sta. Bul.* 47, pp. 90, figs. 92).—Extended series of studies on clover seeds and their impurities are reported. The author has investigated a number of kinds of clover seed and separated from them the different kinds of weed seeds occurring in them. The characteristics of the different clover seeds are figured and described and lists given of the kinds of weed seeds and percentages found in the different samples containing them. Studies are given of alfalfa seed, red clover, white clover, alsike clover, crimson clover, Japan clover, Bokhara clover, yellow sweet clover, yellow trefoil, esparcet, and serradella. From 4 to 90 samples of each of these seeds were examined. The most common weed seeds were *Plantago rugelii*, *P. lanceolata*, *P. aristata*, *Chameraphis viridis*, *C. glauca*, *Polygonum persicaria*, *Chenopodium album*, *Rumex crispus*, *R. acetosella*, and *Euphorbia nutans*. The different weed seeds are figured and described in considerable detail.

Experiments in preserving forest-tree seeds (*Bul. Soc. Cent. Forst. Belg.*, 7 (1900), No. 7, pp. 514-519).—Experiments are reported with acorns and chestnuts, in which the relative efficiency of autumn and spring planting is compared. The autumn plantings were made in two lots, in one of which the acorns were covered with leaves to a depth of from 5 to 6 cm., while in the other they were planted in trenches to a depth of 0.1 meter or a little less. The seeds for spring plantings were preserved as follows: In trenches, in piles covered with soil and others covered with leaves, in baskets submerged in water, and stratified in sand in a dry cave. The results, as shown by the germination and growth of the different lots, are tabulated, from which it appears that in a sandy loam during an ordinary winter autumn seeding is preferred to any of the methods of preserving the seed and planting in the spring. This is shown not only by the fact that more germinations were obtained, but that the work could be done at a season of the year when there was less demand for attention to the nurseries, as is the case in the spring of the year.

The effect of hydrocyanic-acid gas upon the germination of seeds, C. O. TOWNSEND (*Proc. Amer. Assoc. Adv. Sci.*, 48 (1899), p. 297).—Seeds in both a dry and damp state were tested with different strengths of gas and for different periods of time. In the case of dry grains and seeds it was found that they were able to withstand for several weeks an atmosphere of hydrocyanic-acid gas many times stronger than that required for the destruction of insect life. Under these conditions a slightly accelerated germination was observed, and the subsequent growth of the seedlings was slightly above normal. Seeds that had been soaked in water were very sensitive to the presence of the gas. Three one-hundredths of a gram of potassium cyanid per

cubic foot used in generating gas, destroys the germination of seeds that have been soaked for 24 hours in water. The resistance of seeds to this gas seems to be somewhat in proportion to the length of time in which they had been previously soaked.

The germination of ripe and half-ripe dodder seed, W. KINZEL (*Landw. Vers. Stat.*, 54 (1900), No. 1-2, pp. 125-132).—Studies are reported upon the germination of seed of various degrees of ripeness of *Cuscuta epilinum*, *C. epithymum*, *C. planiflora*, and *C. europæa*. It was found that the half-ripe seeds of these species retained sufficient vitality to germinate almost as readily as the fully ripe seed. In some cases they germinated quicker than ripe seeds, and when they were found in their capsules the percentage germination was but little inferior to well-ripened seed. The author says that *C. planiflora* is occasionally found in American clover seed. This seems to be a misstatement, as that species does not appear in any of the recent systematic treatises of the flora of this country. The species is a south European one and its reputed presence is probably due to a wrong determination.

Destruction of weeds in fields of cereals, C. DUSSERRE (*Ann. Agr. Suisse*, 1 (1900), No. 9, pp. 331-337, figs. 4).—An account is given of a number of experiments in which oat fields were sprayed with different strengths of solutions of copper sulphate, iron sulphate, and sodium nitrate, together with mixtures of copper sulphate and sodium nitrate. The best results, so far as weed destruction was concerned, were obtained where the fields were sprayed with a 5 per cent solution of copper sulphate, followed closely by spraying with a 2 per cent solution of copper sulphate and a 10 per cent solution of sodium nitrate. The influence on the oat crop showed a decided stimulating effect where the combination of the copper and soda was employed. The weeds destroyed were mustard, sow thistle, hemp nettle, bind-weed, dock, and various chenopods. Directions are given for the proper application of these herbicides, which should be applied at the rate of 800 to 1,000 liters per hectare. The spraying should be made on a calm, clear day, and should not be delayed beyond the time when the weeds have their first two or three leaves.

Report on seed testing at the agricultural station of Modena for the year 1899, F. TODARO (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 3, pp. 238-258).—A report is given on the activity of the station during the year in testing seeds, and the purity, germinative ability, and intrinsic value of the different samples are shown in tabular form. The principal weed seeds found in a number of different samples are mentioned, and special studies on a number of kinds of seed described.

Seed testing, T. W. KIRK (*New Zealand Dept. Agr. Rpt.* 1900, pp. 299-303).—A tabulated statement is given showing the percentage of germination obtained with the samples tested. While slight improvement in the quality of seed is noted, much weedy and worthless seed is still in the markets of the country.

A new form of seed-sampling apparatus, F. TODARO (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 492-494, fig. 1).—A description is given of the form of apparatus devised by the author for sampling clover and similar seeds.

Troublesome weeds, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1900*, pp. 308-312, figs. 3).—Illustrated notes are given on cape weed (*Cryptostemma calendulacea*), cocklebur or Bathurst bur (*Xanthium spinosum*), and Strathmore weed (*Pimelea* spp.). The latter are reported as poisonous to horses.

Combating weeds by means of chemical agents, J. GRAFTIAU (*L'Ing. Agr. Gembloux*, 10 (1900), No. 6, pp. 413-428).—A review is given of experiments which have been conducted for the destruction of weeds and mosses by means of various chemical solutions. The conclusions drawn by the author are that it is possible to destroy many noxious weeds by spraying with solutions of copper sulphate or of iron sulphate. It is stated that dodder can be successfully combated by spraying with a 3 to 5 per cent solution of copper sulphate.

DISEASES OF PLANTS.

Specimens received for examination by the bacteriological laboratory, F. T. BIOLETTI (*California Sta. Rpt. 1898*, pp. 183, 184, fig. 1).—Miscellaneous notes are given on many specimens and samples which were sent to the bacteriological laboratory for examination. Among some of the more important facts brought out by the examination was the occurrence of leaf spot on violet leaves due to *Cercospora violæ* and *Phyllosticta violæ*. For the prevention of these diseases spraying plants with weak Bordeaux mixture at intervals of ten days is recommended. Specimens of diseased grapevines were sent to the author, in which the main roots were dead and a few small lateral ones remained living. The trunk and branches showed no evidence of disease except in the short growth of the previous year. The roots were covered with a fungus beneath the bark which the author considers the mycelium of some toadstool fungus. The same disease is known to occur in oak trees, and no cure is known when the plant is once thoroughly invaded by it. Preventive measures, such as digging up and burning the diseased parts, are recommended. Brief notes are given on a number of other diseases which are of minor importance.

Concentric spore spots, B. D. HALSTED (*Science*, n. ser., 12 (1900), No. 303, pp. 580, 581).—The author describes the method by which the parasitic fungi reach the surface of their host plants for the distribution of their aerial spores. The most of them have two forms, one in which the exit is made through stomata, the second type embracing those fungi which underlie the epidermis, rupturing it. To the first type belong the Peronosporas, Cercosporas, Ramularias, and Macrosporiums; while to the second type belong the Cystopus, Gleosporium, and many of the rusts. Those fungi that produce their spores through the stomata have their distribution definitely limited. The second type of spore production results in a rupture of the epidermis, and immedi-

ately surrounding this a second line of spore formation is developed in almost a circular form.

The asparagus rust in Iowa, L. H. PAMMEL and E. R. HODSON (*Iowa Sta. Bul.* 53, pp. 60-67, figs. 4).—The authors' attention was called to the appearance of the asparagus rust during the past summer, and early in September the disease was found in considerable quantity in asparagus beds on the college farm. Since that time it has been observed and reported from a number of other stations. The disease is described at some length, and its cause, *Puccinia asparagi*, is figured and described. Two parasites of this rust, *Darluca filum* and *Tubercularia persicina*, are mentioned and briefly discussed. Suggestions are given for preventive measures to be adopted, which consist principally in the propagation of resistant varieties. A short bibliography of the subject completes the bulletin.

Field experiments with tomato rot, F. S. EARLE (*Science, n. ser.*, 12 (1900), No. 303, pp. 579, 580).—A description has previously been given (E. S. R., 12, p. 569) of the bacterial rot of tomatoes caused by an undescribed species of *Bacillus*. In the present paper an account is given of the experiments conducted for the prevention of the disease. In the previous publication the author stated as his belief that the distribution of the disease was largely effected through the presence of thrips, and the experiments here reported were conducted with a view of destroying those insects. Nine plats, with approximately 100 plants each, were the subject of the experiments. Sprayings were made on six of the plats at intervals of 3 to 5 days with kerosene, whale-oil soap, and "Rose Leaf" tobacco extract, eight applications in all being given to the plants. All of the fruits were gathered and the presence of disease noted. The rotted fruits varied from 12 to 27 per cent on different plats, the highest amount of disease occurring in one of the check plats, as well as the lowest percentage. The figures given were slightly in favor of the tobacco extract treatment. This treatment gave 5 per cent less of diseased fruits than the average of all plats; but as there was a range of 15 per cent between the highest and lowest of the check plats, the author considers the experiments inconclusive. There was an almost total absence of thrips in a fair season, and on this account some other means will have to be discovered for the spread of the disease.

The brown rot of peaches, plums, and other fruits, A. L. QUAINANCE (*Georgia Sta. Bul.* 50, pp. 237-269, figs. 9).—The brown rot of peaches and plums has been the cause of serious loss to commercial growing of these fruits in Georgia, and the author has been led to make an extended investigation as to its cause and means for prevention. The cause of this well-known disease is the fungus *Monilia fructigena*, which is distributed widely over the United States and Europe. In the United States it is particularly disastrous to stone

fruits, the pomaceous fruits suffering but slight loss. In Europe the fungus is said to occur on plums, cherries, apricots, peaches, apples, and pears. While usually occurring upon the fruit, it also affects the flowers and twigs. The life history of the fungus is described at considerable length, and the author states that while there is some evidence that the summer spores survive the winter, yet the principal source of infection in the spring is the shriveled dried fruit commonly known as "mummies," which occur on the trees and upon the ground under them.

Results of spraying experiments for the prevention of this disease are outlined, in which cooperative experiments on large numbers of trees and experiments conducted at the station are described. The best fungicides for use in spraying proved to be Bordeaux mixture, composed of 3 lbs. of copper sulphate, 6 lbs. of lime, and 50 gal. of water. Directions are given for the proper preparation and application of the fungicide. Three applications of Bordeaux mixture, the first given just before blossoming, and a fourth spraying of copper acetate solution given when the fruit begins to color, has proved the most advantageous treatment in the author's experience. By this treatment the disease was almost entirely controlled, at a cost of chemicals and labor not to exceed 6 cts. per tree for four applications.

The leaf-spot disease of cherry trees, MÜLLER-THURGAU (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1897-98, pp. 103-107.*)—The common occurrence of a fungus, *Clasterosporium amygdalearum*, upon the leaves of a cherry was noted. In addition to occurring on the leaf, it is also found on the fruit and stems, and has a wide distribution throughout parts of Europe. For combating this disease, the choice of resistant varieties and individuals is recommended, as well as the increased virility of plants by stimulating them with fertilizers. Cutting out of badly diseased parts of trees and the working over of the soil and destruction of refuse under the trees, are suggested. Spraying beneath the trees and on the twigs before blossoming with $\frac{1}{2}$ to 1 per cent solutions of Bordeaux mixture is also suggested.

The author reports the occurrence of the mycelium of *Monilia fructigena* in the twigs of apples.

Spot disease of the violet, P. H. DORSETT (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 23, pp. 16, pls. 7.*)—The author describes a spot disease of the violet, which has proved to be of serious effect in a number of houses, where violet cultivation has practically been abandoned on this account. The disease is due to *Alternaria violæ*. It attacks the plants at any stage of their growth, from a small unrooted cutting to a mature plant; and those plants making the most vigorous and rapid growth are most subject to the disease. Any part of the plant above the soil is subject to attack, and the first appearance of the disease upon the leaves may be recognized

by small, definite, circular, greenish or yellowish-white spots, varying in size from mere specks to spots $\frac{1}{32}$ in. or more in diameter. Frequently a number of such areas occur upon the same leaf, and the disease spreads until the entire leaf is destroyed. Various previous theories as to the cause and treatment of the disease are discussed, and the parasitic nature of it is shown by the author's investigations, in which artificial inoculations have been successfully made. The fungus, which is a new species, is technically described, and the varying susceptibility of different varieties is noted. Preventive measures are suggested which contemplate the keeping of plants in a healthy condition, propagating from only healthy, vigorous stock, as the best possible means. The experiments conducted with fungicides seem to show that they possess little value in preventing this disease, while rendering the foliage worthless for bunching with the flowers. The most practical means for preventing the disease appears to be in the development of strong plants which are resistant to the attacks of the fungus.

An anthracnose and a stem rot of *Antirrhinum majus*, F. C. STEWART (*Science, n. ser., 12 (1900), No. 303, p. 581*).—A brief account is given of two diseases of snapdragons—one an anthracnose caused by a *Colletotrichum*, and a stem rot due to an undetermined species of *Phoma*. The *Colletotrichum* produces elliptical depressed spots on the stems and circular dead brown spots on the leaves, and is very destructive to plants in both greenhouse and field, and at all seasons. It was found due to a new species of fungus, to which the name *C. antirrhini* was given. This disease may be successfully combated by spraying the plants once a week with Bordeaux mixture. The stem-rot disease attacks the stem, causing sections an inch or more in length to turn brown or black. This attack may occur at any point above the ground, and is usually observed a few inches below the tops of succulent shoots. Inoculation experiments show that the fungus is an active parasite of succulent shoots, but attacks woody stems with difficulty.

Experiments in the preparation of Bordeaux mixture, W. KELHOFFER (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1897-98, pp. 57-68*).—Experiments were conducted to ascertain the effect of a number of factors upon the composition of Bordeaux mixture, as shown by the separation of the different mixtures upon standing. Among the experiments were those to determine the effect of iron sulphate, which is commonly present in commercial copper sulphate; upon different quantities of copper sulphate; different quantities and qualities of lime; different concentrations of mixtures; order of combining the solutions; and temperature of solutions. The presence of iron sulphate was found to cause a more rapid separation of the liquid. Within the limits of the experiments, separation was inversely

proportional to the amount of copper sulphate used. The quality of lime affected the mixture very appreciably, the mixture containing the best lime precipitating the slowest. The proportion of lime exerted the same effect as the amount of copper. Fresh, well-slaked lime gave a better mixture than poorly slaked, but fresh air-slaked lime was about its equal. Older air-slaked lime produced a mixture that separated very rapidly. Allowing the milk of lime to stand for two days was practically without effect upon the different mixtures, the results with milk of lime which had been exposed to the air being almost identical with freshly made. Bordeaux mixture made by pouring the lime into the copper solution was much inferior to the others. Where the copper mixture was poured into the lime and where both mixtures were poured into a third vessel, the mixture was about the same. Heat was found to cause a separation in the mixture in proportion to the increase of temperature.

Monilia diseases, P. SORAUER (*Ztschr. Pflanzenkrank.*, 10 (1900), Nos. 3-4, pp. 148-154; 5, pp. 274-284, figs. 2).—In continuation of a previous article (E. S. R., 11, p. 949), the author describes the diseases caused by *Monilia* on cherries, prunes, hazelnuts, and upon the twigs of apple, pear, etc. Numerous inoculation experiments are reported, in which it was found possible to transfer the fungus from the apple to the hazelnut, cherry, apricot, and grape; and from a hazelnut to the apple, prune, haw, and grape. In the last case the development was meager and inoculation often failed. In the second part of the paper a description is given of the action of the fungus upon twigs of the apple, pear, etc.

Die-back disease of apricots, E. M. SAGE (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 5, pp. 425-428, figs. 2).—An account is given of a disease of apricot trees in which the limbs were slow in starting out one season and the following year began to die back a distance of 1 to 3 ft. from the end, in some cases the entire limb dying. The trees had been planted on rather poor soil, and the author attempted to restore their vitality by the use of fertilizers. It was found that liberal applications of bone superphosphate produced a decided improvement in the condition of the trees.

The olive knot, F. T. BIOLETTI (*California Sta. Rpt. 1898*, p. 178, fig. 1).—In Bulletin 120 of the station (E. S. R., 10, p. 55) an account is given of the occurrence, symptoms, and distribution of the olive knot in California. In the present publication a brief account is given of successful inoculation experiments, which proved that the disease is of a contagious nature and that it is due to a specific bacterium.

Experiments in combating some diseases of grapes, apples, and pears, K. MOHR (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 5, pp. 270-274).—An account is given of spraying grapes, apples, and pears for the prevention of the powdery mildew of the grape and scab of apples and pears. A compound of Bordeaux mixture and sulphur, and a solution of basic calcium sulphid, were used. For the grape mildew the author stated that Bordeaux mixture alone is of little value, the sulphur compounds being much preferable. The results of his experiments showed the value of the mixtures in which sulphur entered in different forms.

The influence of winter on the fungus diseases of grapes, H. SCHLEGEL (*Weinbau u. Weinhandel.*, 1900, No. 13, pp. 117-118).

The grape mildew and its prevention, STEGLICH (*Sächs. Landw. Ztschr.*, 48 (1900), No. 18, pp. 193-195).

Concerning the fungus which causes the black rot of grapes, A. VON JACZ-YESKI (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 5, pp. 257-267, figs. 8).—The author has reported the results of studies on the causes of the black rot of grapes, from which

he concludes that this disease is caused by three specific organisms. In the Caucasus region it is due to *Guignardia baccæ*, while in France it is caused by *G. bidwellii*. In Germany and Switzerland he has not been able to find either of these fungi, and thinks doubtless that the disease is due to a third species. An interesting point brought out in the investigation is that the general characteristics of the fungi are alike, and in practice the same treatment applies to all.

On the occurrence of Peronospora on flowers and young fruit of grapes, MÜLLER-THURGAU (*Jahresber. Vers. Stat. u. Schule, Wädenswil, 1897-98*, pp. 101-103).—The author reports having observed the presence of *Peronospora* upon the flowers and newly formed fruits of grapes. These appeared before the usual time for the first spraying, and the author believes that means should be taken for the destruction of the *Peronospora*, so that the winter spores may not be carried over to infect the plants in the spring.

Combating Oidium and Peronospora, KULISCH (*Landw. Ztschr. Elsass-Lothringen, 1900, Nos. 21, pp. 294, 295; 22, pp. 307, 308*).

Combating Oidium, J. BEHRENS (*Wechbl. Landw. Ver. Baden, 1900, No. 11, pp. 144, 145*).

Investigations on the forms of sulphur used in viticulture, C. DUSSEY (Ann. Agr. Suisse, 1 (1900), No. 9, pp. 327, 330).—An account is given of investigations of different forms of sulphur used for the prevention of grape oidium. The usual forms are sublime and triturated. A third form which recently appeared on the market is known as aerated sulphur. The physical condition of these different kinds was investigated at considerable length and is reported upon.

Recent investigations on diseases of tropical economic plants (*Ztschr. Pflanzenkrank., 10 (1900), No. 5, pp. 288-292*).—Brief notes are given, in which a number of diseases and insects of economic plants of the tropics are described, together with means that have been adopted for their destruction. The host plants mentioned are coffee, tea, cacao, sugar cane, sorghum, vanilla, St. John's bread, cocoanut palm, caoutchouc, ramie, and grapes.

The parasitism of Ximenia americana, E. HECKEL (*Compt. Rend. Acad. Sci. Paris, 131 (1900), No. 19, pp. 764, 765*).—The results of some experiments on the part of the author to infect a number of trees with this parasite are given. It was found that it was parasitic only on *Ficus laurifolia*.

Concerning the parasitism of Botryosporium, V. PEGLION (*Staz. Sper. Agr. Ital., 33 (1900), No. 6, pp. 585-589*).

A fungus disease of Casuarina, A. VON JACZEWSKI (*Ztschr. Pflanzenkrank., 10 (1900), No. 3-4, pp. 146-148, fig. 1*).—A brief account is given of an attack of *Botryosporium diffusum* on the twigs of *Casuarina leptoclada*. The fungus, which is usually a saprophyte, occurs here as a parasite, and its method of growth is described.

Carnation-stem rot, F. W. CARD and G. E. ADAMS (*Rhode Island Sta. Rpt. 1900, pp. 249-251*).—Experiments begun in 1899 (E. S. R., 12, p. 763) were continued. The principal point under consideration is a comparison of the effect of chemical v. stable manure as a fertilizer for these plants. The statement in the previous report is reaffirmed that new, clean sand bearing no trace of disease, and the use of soil in which carnations have not previously been grown, are the most important conditions to be secured. The experiments so far do not bear out the prevalent opinion that stable manure favors the spread of disease.

ENTOMOLOGY.

Foul brood of bees, F. C. HARRISON (*Centbl. Bakt. u. Par., 2. Abt., 6 (1900), Nos. 13, pp. 421-427; 14, pp. 457-469, figs. 4; 15, pp. 481-496; 16, pp. 513-517*).—The author presents a critical review of the literature of foul brood in connection with a bibliography of 80 titles.

The symptoms of foul brood are described in detail and the disease is distinguished from chilled brood. Some writers have suspected that foul brood varied in different countries, but no bacteriological work has been done to substantiate this view. The author examined diseased larvæ from France, Switzerland, Austria, Germany, Italy, England, Cuba, and 13 States in this country, with the result that *Bacillus alvei* was isolated from every case. Slight differences were noted in the cultures, but not sufficiently pronounced to constitute a well-marked variety of the species. The pathogenicity of *B. alvei* varies in different countries and is especially virulent in new countries. The author describes in detail the different morphological and biological characters of *B. alvei*, including notes on staining methods, the germination of spores, polymorphism, and variations in the growth of the bacillus upon a large variety of culture media. In experiments to determine the relation of the bacillus to free oxygen, spores obtained from a pure culture on agar were spread on cover glasses and placed in a glass chamber so that they were constantly exposed to a current of air. The chamber was exposed to the ordinary light of a room. A cover glass was taken out every 24 hours and tested to determine whether the spores would grow. The experiment was continued for the period of a month and at the end of that time the spores still germinated rapidly. When grown on bouillon *B. alvei* produced a slight amount of ammonia. A varying amount of acid is formed in all sugar bouillon cultures of the bacillus. On potatoes a yellow pigment was produced and on gelatine cultures a peculiar odor was given off. The spores on cover glasses exposed to sunlight in September germinated after 4, 6, and 7 hours' exposure.

Experiments were conducted for the purpose of determining the thermal death point of spores of this bacillus. Test tubes containing inoculated bouillon were placed in boiling water, removed at stated intervals, cooled, and incubated. Spores from a 7 months' old culture were killed by a temperature of 100° C. for 1 hour and 20 minutes. Spores from an agar culture 9 days old germinated to some extent after an exposure of 2 hours and 45 minutes to the same temperature. Experiments were also made to determine the thermal death point of *B. alvei* in honey, during which 3 methods were used: Silk threads with dried spores on them, test tubes containing honey inoculated with spores, and capillary tubes containing a suspension of spores in distilled water. The honey was of 2 kinds, clover and buckwheat, containing 0.057 per cent and 0.17 per cent of formic acid. By the first method, there was considerable growth after 2 hours' exposure at a temperature of 114° C.; by the second method, no growth took place after exposure of $2\frac{1}{2}$ hours to a temperature of 115° C.; while by the third method no growth took place after an exposure to the same temperature for 2 hours and 45 minutes.

In order to determine the relation of *B. alvei* to light, cover glasses

spread with spores and dried were exposed to direct sunlight in February. The temperature during the experiment varied from -12 to -22°C . After exposure, the cover glasses were placed film side down on agar and incubated at 37°C . Abundant growth took place within 16 hours of the different lots of spores which had been exposed to sunlight for 3, 6, and 9 hours.

Cultures of *B. alvei* were found to live longer on agar than in liquid media. The author discusses the economic aspects of foul brood and the losses due to this disease in different countries. It was observed that after a prolonged cultivation of *B. alvei*, in which more than thirty transfers had been made, the virulence of the germ seemed to be considerably decreased. The author believes that the chief method of carrying the disease from one hive to another is by bees from healthy hives robbing colonies that have become diseased. A weak and badly nourished condition of a colony of bees is considered a predisposing cause to infection by foul brood.

Remedies against foul brood are classified into three groups: The stamping-out system, starvation methods, and treatment by chemicals. In the stamping-out system, affected bees, combs, and frames must be destroyed and the hives thoroughly disinfected. By the starvation method, combs are removed and the bees allowed to fast for 2 days or more, after which they are introduced to clean new combs and fed on sirup prepared from hot water mixed with honey, nutmeg, and saffron. Since this original starvation method was proposed, various modifications of the method have been elaborated and applied in the United States and Europe. In the use of chemicals for the treatment of foul brood, the object is to secure a substance which will destroy or prevent the growth of *B. alvei* in the bees without injuring the latter. In this way the following substances have been used: Carbolic acid 1:600 of sirup; or a deciliter of carbolic acid in sirup and a liter of water thoroughly shaken together; salicylic acid, salicylic-acid vapor, camphor, thyme, thymol, carbolic acid and tar, creolin, eucalyptus, naphthol β , naphthaline, and formic acid. In experiments with these substances the various chemicals have been used both as external antiseptics and in the food of bees. Formic acid probably helps the bees to ward off an attack of foul brood. This substance is a natural constituent of honey, and it was found that the spores of the *B. alvei* develop less vigorously after cultivation on agar containing formic acid.

The author conducted experiments on the use of drugs for preventing the disease. Two small hives containing strong healthy swarms were selected for this purpose and placed side by side. Hive A was given spores of *B. alvei* in sirup containing $\frac{1}{3}$ gm. of naphthol β to a liter, while hive B was fed spores in sirup containing from 1.6 to 1.8 cc. of formic acid to the liter. The spores were poured into the

medicated sirups and the mixtures thoroughly stirred. They were readily accepted by the bees. The bees were fed 4 days per week for 3 weeks and at the end of the period none of the ordinary symptoms of foul brood had appeared. The medicated sirup was discontinued for a week and then ordinary sirup containing spores was fed. Typical symptoms of foul brood developed within 10 days, and within 16 days the disease was well established. The author tried an experiment in feeding the filtrate from a 2 weeks' old culture of *B. alvei* in saccharose bouillon mixed in sirup, in order to determine whether any increased resistance or immunity against foul brood could be produced. After 3 weeks of this treatment, spores of the bacillus were fed to the bees, with the result that foul brood developed within 14 days. Brief notes are given on the foul brood laws in force in the United States.

The action of different rays of the solar spectrum on the development of silkworms, C. FLAMMARION (*Bul. Min. Agr. [France]*, 19 (1900), No. 5, pp. 865-868).—The author experimented upon 720 silkworms, which were placed in 12 boxes and subjected to different colored lights. The silkworms were 6 days old when the experiment began. The results of these experiments are tabulated in detail, and the more important ones may be stated as follows: The maximum production of silk took place under plain, colorless glass; the next best production of silk was obtained under clear, violet purple glass and the smallest under a dark blue glass. A rather pronounced influence was noted in different colored rays upon the determination of the sex of silkworms. Under the colorless glass the number of females was 56 per 100, while under the blue glass it was 37 to 100. The author suggests that this may be interpreted as meaning a variation in the nutrition of the silkworms under the influence of different colored lights.

Experiments in protecting man against mosquitoes by chemical agents, C. FERMI and C. LUMBAAO (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 6-7, pp. 186-189).—Experiments were conducted for the purpose of discovering substances which could safely be used upon the exposed parts of the body and which would kill mosquitoes. These experiments, however, did not yield promising results and were discontinued.

A number of experiments were tried in the destruction of mosquito larvæ in ponds of water. The substances used included lanolin, lard, olive oil, castor oil, vaselin, petroleum, eucalyptus, verbena, tobacco, onions, wormwood, acetic acid, carbolic acid, salicylic acid, and extracts from animals which are resistant to mosquitoes. Besides the experiments with simple substances, a number of other experiments were tried with combinations of two or more substances. Of the nearly 400 remedies which were thus tried, the following were the only ones which gave satisfactory results: Castor oil, vaselin, allyl sulphid, and benzine aldehyde, $2\frac{1}{2}$ per cent; water and eucalyptus, $2\frac{1}{2}$ per cent;

vaselin, lanolin, and allyl sulphid, 1 per cent; tar water, eucalyptus, and kummel, 10 per cent.

The "silver top" condition of meadow grasses in Finland, E. REUTER (*Acta Soc. Fauna et Flora Fennica*, 19 (1900), No. 1, pp. 136, pls. 2).—This article is in the nature of a monographic account of the insect attacks which result in the blasting of the heads of grasses. The author's observations are confined chiefly to *Phleum pratense* and *Alopecurus pratensis*. An elaborate classification is given of the insect attacks which cause these conditions, the classification being based on the method of attack and upon the part of the plant attacked. The author gives a review of previous investigations on this subject in other countries, together with notes on the grasses affected and on the insects which cause the damage. Among the insects which are responsible for the silver top condition in Finland may be mentioned *Hadena secalis*, *H. strigilis*, *Tortrix paleana*, *Pediculoides graminum*, *Aptinotherips rufa*, and *Tarsonemus culmicolus*. The last-named species and *Pediculoides graminum* are described as new. *P. graminum* was found to be very destructive to grasses. Pregnant females of this species were first found in the middle of July on *Phleum pratense*. From this time until fall such individuals were found in considerable numbers, especially on *Agropyrum repens*. These females attach themselves to the stems of grasses and remain so attached until their death. The author made numerous observations on the relative numbers of the two sexes of this species, and found that there appeared to be no males during the first half of the summer and that during the second half of the summer they were comparatively rare. From observations made in the field and laboratory, the author believes there are two complete generations of this insect annually. Besides the species already mentioned, the author gives notes on a number of others which are of less importance in causing the silver top condition. The complete list as studied by the author includes 4 species of Thysanoptera, 5 of Lepidoptera, 6 of Diptera, 2 of Hymenoptera, 1 of Hemiptera, and 4 species of mites. An extended bibliography is given of the literature relating to this subject.

The strawberry-root louse; the destructive pea louse in Delaware, E. D. SANDERSON (*Delaware Sta. Bul.* 49, pp. 24, figs. 7).—The author gives notes on the habits and life history of *Aphis forbesi*, and describes the preventive remedies which have given best success in combating this insect. Among such remedies mention may be made of the use of uninfested plants, rotation of crops, and disinfection of strawberry plants by dipping in kerosene emulsion or tobacco water, or by fumigation with hydrocyanic-acid gas.

Notes are given on the occurrence of the destructive pea louse in Delaware. Its preferred food plant is said to be crimson clover. An experiment was tried in spring on an acre of infested peas with a

25 per cent mixture of kerosene and water. The majority of the lice were killed, but the author does not consider this method as capable of practical use on a large scale. He believes that the destructive pea louse is a well-known insect, described under the name *Nectarophora pisi*.

Supplement to my article on "American fruit and its parasites," C. BRICK (*Bot. Mus., Abt. Pflanzenschutz, Hamburg, 2 (1899-1900), pp. 19*).—In this article the author gives an account of the amount of fresh and dried American fruit received in Hamburg, and indicates the percentage of such fruit infested by various scales and fungus diseases. The San José scale was found infesting 3.12 per cent of 82,802 packages of fruit. Of the apples which came from the eastern part of the United States, 1.84 per cent were infested, while the California apples showed an infestation of 42.44 per cent and the Oregon apples 51.44 per cent. In infested packages the lowest infestation was 1 per cent, while in many cases almost every apple in the package was infested with the scale. In 23 shipments from Eastern States which were infested with the San José scale, *Aspidiotus forbesi* and the scurfy scale were also found.

As bearing upon the question of the origin of the San José scale the author reports that this insect was found upon the following species of living plants imported directly from Japan, viz: *Prunus mume*, *P. mume pendula*, *P. pendula*, *P. persica*, *P. pseudo-cerasus*, *P. cerasus*, *Citrus trifoliata*, and *Salix multinervis*. On some of these plants San José scale was found in all of its stages. Among the other insect parasites and fungus diseases which were found on the American fruit the following may be mentioned: Forbes scale, scurfy scale, oyster-shell bark-louse, *Aspidiotus ancyclus*, *A. camelliae*, *Gymnosporangium macropus*, and *Capnodium salicinum*.

The San José scale was found on 20 crates of pears from California. In shipments of dried fruit the San José scale was found infesting 3,052 crates of pears and 50 crates of nectarines. Besides other species of scales already mentioned, *Diaspis fallax* was found on apricots.

Crude petroleum v. the San José or pernicious scale, J. B. SMITH (*New Jersey Stat. Bul. 146, pp. 20*).—In this bulletin the author summarizes the general results of his experiments with crude petroleum as an insecticide against the San José scale since 1897. More than 50,000 fruit trees of different kinds have been sprayed with crude petroleum under the direction of the author or have been subsequently inspected by him. In investigating the cause of damage to trees from crude petroleum in the hands of certain experimenters, the author found that the name crude petroleum had no definite meaning and included a number of oils of very different specific gravity. The one with which the author's experiments were conducted had a specific gravity of 43 per cent and was of a dark green color. Some inter-

mediate oils were found with a specific gravity as low as 35 per cent. This last specimen was almost uniformly fatal to foliage. Further study revealed the fact that even true crude oils differ considerably in color, specific gravity, and otherwise. In studying the difference between crude oils the author found that as a rule when oil wells were shot and the surrounding trees were covered with crude oil no damage to the foliage resulted.

Details are given of a number of additional experiments with crude oil by the author and fruit raisers. The author used this substance on peach, pear, apple, plum, and cherry trees without causing any harm. One branch of a cherry tree was painted with an intermediate oil with a specific gravity of 35 per cent and another branch of the same tree with a crude oil of 43 per cent on the same day. The former branch died and the latter developed flowers normally. Near Riverton 25 bbls. of crude oil were sprayed on apple, pear, and peach trees and currant and gooseberry vines. No injury was produced on any variety. Experiments in spraying Japanese walnuts, native butternuts, and chestnut trees with crude oil resulted in serious injury to all the trees. Details are given of a number of other experiments by fruit raisers with varying results as to injury to the trees. The author discusses the subject of the action of the oil, method of applying it, the reliable firms of whom oil may be purchased, and its range of usefulness. It is stated that crude petroleum should be used as an insecticide in winter applications only. Summer treatment for San José scale may be made with tobacco extracts and fish-oil soaps. The author concludes that the San José scale can be as certainly controlled as many other injurious insects and that crude petroleum of the proper quality, rightly used, "forms a reasonably safe, economical, and effective material for the purpose." These conclusions are for Atlantic States and should not be relied upon in arid regions without further experiments.

A report on the scientific works on entomology during 1898, R. LUCAS and G. SEIDLITZ (*Arch. Naturgesch.*, 65 (1899), II, No. 2, 1. half, pp. 330).—In the first part of this report a bibliographical list is given of articles on entomology published in 1898. In the second part of the report, articles dealing with Coleoptera are listed alphabetically under the authors' names, geographically according to countries and periodical publications, and also according to subjects. The references to American literature on entomology, especially to experiment station publications, are very incomplete, only a few of such bulletins being mentioned.

The century's work among the aculeate Hymenoptera, F. D. MORICE (*Ent. Rec. and Jour. Variation*, 13 (1901), No. 1, pp. 12-14).—Brief notes on the more important publications on this group of insects.

The Lepidopterological books of the nineteenth century, L. B. PROUT (*Ent. Rec. and Jour. Variation*, 13 (1901), No. 1, pp. 20-25).—This article contains a brief discussion of the literature of this subject, with bibliographical references.

The progress of our knowledge of the dragon flies during a century and a half, W. F. KIRBY (*Ent. Rec. and Jour. Variation*, 13 (1901), No. 1, pp. 7-11).—The author classifies the more important literature on this subject into a Linnean period

and a modern period, embracing general works on dragon flies, works relating to European dragon flies, to British dragon flies, and to American dragon flies.

Evolution of our knowledge of the Ichneumonidæ during the nineteenth century, C. MORLEY (*Ent. Rec. and Jour. Variation*, 13 (1901), No. 1, pp. 15-18).—The author illustrates the progress made in the knowledge of this group of insects by references to the more important literature on the subject.

A study of the structure of the ocelli of insects, W. REDIKORZEW (*Ztschr. Wiss. Zool.*, 68 (1900), No. 4, pp. 580-624, pls. 2, figs. 7).—The author discusses in detail the microscopical elements of the simple eyes in insects. Material for this study was obtained from a number of species, of which mention may be made of the honeybee, syrphus flies, and species of *Cimbex* and *Perla*. A bibliography of the subject is appended to the article.

Parthenogenesis in bees, A. WEISMANN (*Anat. Anzeiger*, 18 (1900), No. 20-21, pp. 492-499).—The author discusses in a general way the factors which have been supposed by different authors to be concerned in determining the sex of different members of the bee colony.

The treatment of foul brood by eucalyptus, salicylic acid, and formic acid, J. B. GRAMONT (*Rev. Internat. Apicult.*, 22 (1900), No. 10, pp. 225, 226).—From observations and experiments the author concludes that the most effective and convenient method of treating hives infected with this disease is by the use of formaldehyde.

The use of honey, J. CRÉPIEUX-JAMIN (*Rev. Internat. Apicult.*, 22 (1900), No. 10, pp. 206-210).—The author reports a number of cases in which honey was eaten in considerable quantities after fatiguing exercise. The results indicated a beneficial effect from the honey.

The common European praying mantis, a new beneficial insect in America, M. V. SLINGERLAND (*New York Cornell Sta. Bul.* 185, pp. 33-47, figs. 14).—This insect has recently been discovered in the neighborhood of Rochester, N. Y., and it is believed that the species was introduced into this country by a nurseryman. Brief notes are given on its habits and life history.

Report of the entomologist, L. BRUNER (*Nebraska State Bd. Agr. Rpt. 1899*, pp. 103-142, pls. 16).—In this report the author discusses in a popular manner the insects which are injurious to native grasses on prairies and in meadows. Especial attention is given to the leaf hoppers, and a brief bibliography is presented on the insects which affect grasses. W. D. Hunter presents an additional list of insects injurious to clover and alfalfa.

Report of the zoologist, H. B. WARD (*Nebraska State Bd. Agr. Rpt. 1899*, pp. 193-205, figs. 6).—This report contains an account of the ticks of Nebraska. An analytical table for the determination of species is given, and notes are presented on the life history and habits of *Argas americanus*, *Ornithodoros megnini*, *Dermacentor americanus*, *Boophilus bovis*, *Ixodes reduvius*, and *Amblyomma americanum*.

Report on the work of the State entomologist for the year 1899, S. LAMPA (*Ent. Tidskr.*, 21 (1900), No. 2, pp. 49-96).—The author gives a detailed account of the office of the State entomologist. It is stated that *Pyrethrum roseum* has been grown successfully on the grounds near the office, with the result that a sufficient quantity of pyrethrum powder has been manufactured for a year's supply. The Hessian fly and *Chlorops pumilionis* are reported as causing considerable damage in the region of Gotland. Great destruction was wrought by *Lynmantria monacha*. An assistant conducted a number of spraying experiments with a 2 to 4 per cent solution of lysol in water and with a kerosene emulsion. The buds of fruit trees were not injured by a 1 per cent solution of lysol.

Brief notes are given on the habits and life history of *Hadena basilinea*, *Tipula oleracea*, *Agriotes lineatus*, *A. segetum*, cabbage-root maggot, *Psila rose*, *Charaxes graminis*, *Argyresthia conjugella*, codling moth, and numerous other injurious insects.

Observations on insects, T. D. A. COCKERELL (*New Mexico Sta. Bul.* 35, pp. 27, figs. 10).—This bulletin contains brief popular notes on a number of economic insects, among which mention may be made of *Scelopendra heros*, *Bryobia pratensis*, *Apis dorsata*, pear slug, striped cucumber beetle, *Epitrix cucumeris*, *Epilachna varivestis*, harlequin cabbage bug, squash bug, false chinch bug, and woolly aphid.

Experimental entomology, F. MERRIFIELD (*Ent. Rec. and Jour. Variation*, 13 (1901), No. 1, pp. 26-31).—The author calls attention to the necessity for more careful observations under experimental conditions on the habits and life history of economic and other insects.

Insects injurious to cereals, V. MAYET (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 49, pp. 691-698, pl. 1).—The author discusses the life history and habits of *Crioceris melanopa*, *Hippopsis gracilis*, *Tenebrio molitor*, and *Agriotes lineatus*. Brief notes are given on the remedial measures which have been most effective in combating the attacks of these insects.

The life habits of certain grasshoppers, R. TÜMPER (*Allg. Ztschr. Ent.*, 6 (1901), No. 1, pp. 3-7).—The author relates his observations on the habits and life history of *Locusta viridissima*, *Decticus verrucivorus*, and *Meconema varium*.

On locust destruction (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 9, pp. 535-540, figs. 2).—The following methods for destroying locusts are recommended: The use of canvas screens with a strip of oilcloth $4\frac{1}{2}$ in. wide sewn on the top of the canvas so as to direct the locusts into pits, where they are destroyed; trampling by herds of sheep or goats; dragging with bushes; beating with flails; and the use of the locust fungus. Mention is made of an insect enemy of the locust known as *Cynomia pictifacies*.

Locust destruction (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 10, pp. 619, 620, fig. 1).—An account of brief reports by C. W. Sparkes and Mr. Halse concerning the distribution of locust fungus and the use of a bush harrow in destroying the young locusts.

The apple maggot, F. W. CARD and G. E. ADAMS (*Rhode Island Sta. Rpt.* 1900, pp. 247, 248).—Observations were made upon the effect of plowing underneath trees on the prevalence of this insect. At first results were obtained which seemed to be very promising, but on September 19, 1899, 500 apples from the trees which were under treatment and an equal number from a neighboring tree the ground under which had not been plowed were examined, with the result that 236 apples of the first lot and 394 of the second lot were found affected. The infestation in the first lot of apples was, however, not so serious as in the second lot, and the authors believe that the method offers some encouragement.

The grape-root worm, a new grape pest in New York, M. V. SLINGERLAND (*New York Cornell Sta. Bul.* 184, pp. 17-32, figs. 10).—A report of an insect injurious to grapes at Ripley, in the Chautauqua Lake grape region, was sent to the author in September. An examination of the vineyard showed that it was set in fertile soil and had had good care. The leaves on affected vines showed the effects of the insects' attack in the form of small holes. A number of larvæ were found at work on the roots of such grapevines, and it is believed by the author that the species is *Fidia viticida*, although no specimens were reared to maturity. Brief popular notes are given on the life history and habits of this insect.

Tortrix ambiguella and T. pilleriana, J. JABLONOWSKI (*Kisérlet. Közlem.*, 3 (1900), No. 4, pp. 269-360, pls. 3, figs. 8).—The author reviews a part of the literature which deals with these two species, and gives a detailed account of their anatomy, life history, habits, and food plants. Among the natural enemies of *T. ambiguella* the author mentions *Anomalon flavolatum*, *Vespa vulgaris*, and a bacterial disease apparently due to the attack of a micrococcus. Among the artificial remedies which were tried against these insects, mention may be made of the kerosene lamp and pyrethrum. The synonymy of both species is discussed in considerable detail. *T. ambiguella* is said to be double-brooded in Hungary, while *T. pilleriana* has but one

brood annually. Both species are permanently established in the vicinity of vineyards and become periodically from 4 to 5 times as numerous as usual and correspondingly injurious.

The rôle of insects in the forest, J. B. SMITH (*Rpt. State Geol. New Jersey, 1899*, pp. 205-232, figs. 9).—The author gives popular accounts of a number of injurious forest insects, among which mention may be made of gall wasps, the tulip soft scale, bark beetles, ambrosia beetles, *Prionoxystus robinæ*, and *Lyctus striatus*. The agency of birds in destroying forest insects is briefly discussed by the author, and notes are also given on the more common insecticide methods for destroying such insects.

An outbreak of *Psilura monacha*, E. WÖHL (*Illus. Ztschr. Ent.*, 5 (1900), No. 23, pp. 364-366).—This insect is reported as having been unusually injurious for the past 5 years in the forests of Oberslesien. The area which is specially devastated by the species includes several square miles. In localities where the injuries were unusually severe, attempts were made to check the insect by collecting the eggs and larvæ and by the use of tar bands upon the trees. These methods, however, did not prove very effective.

Cyanid of potash as a remedy for phylloxera, *Mytilapsis fulva*, and *Parlatoria ziziphi*, G. FLORIANO (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 1, pp. 5-18).—The author tried a number of experiments in inoculating cyanid of potash into grapevines and citrus trees for the purpose of determining the extent to which it is absorbed by the juice of the plant and whether it would kill insects which were feeding upon plants at such times. When the cyanid of potash was applied at the vintage term it was absorbed quite abundantly by the grapevines and distributed both upward and downward from the point of inoculation. It was observed, however, that the phylloxera continued to develop and multiply as on vines which were not treated. When cyanid of potash was applied as a remedy against *M. fulva* and *P. ziziphi* on citrus trees no benefit was observed; the plants were somewhat damaged and the insects were not affected.

Sprays and washes, C. W. WOODWORTH (*California Sta. Rpt. 1898*, pp. 181, 182).—The author gives formulas and directions for preparing Paris green, kerosene emulsion, rosin soap, lime salt and sulphur, sulphid of potash, Bordeaux mixture, and ammonia copper carbonate.

Experiments with insecticides and fungicides, N. G. MUKERJI (*Ann. Rpt. Sibpur Expt. Farm, 1899-1900*, pp. 9, 10).—In combating the attacks of *Hispa anescens* upon paddy, experiments were tried with a knapsack vaporizer and a number of spraying bellows. The insecticides which were used included tobacco decoction, kerosene emulsion, turmeric dust, and a powder containing ashes, lime, arsenic, soot, and asafetida. The last-named insecticide seemed to be very effective.

The orchard and nursery inspection law (*Ohio Sta. Rpt. 1900*, pp. XXVII-XXIX).—This is a copy of a law recently passed in Ohio to prevent the introduction and spread of the San José scale, other dangerous insects, and contagious diseases affecting various trees and plants.

FOODS—ANIMAL PRODUCTION.

Report of the analyst [on the adulteration of food and drug inspection] (*Massachusetts State Bd. Health Rpt. 1899-1900*, pp. 603-652).—Of the 4,435 samples of milk analyzed, 27.2 per cent were found to be adulterated, and of the 2,615 samples of foods other than milk, 14.8 per cent. In addition to other data relating to the subjects discussed, the composition of a considerable number of samples of condensed milk is reported.

In investigating the possibilities of tin from cans being dissolved in fruit juice or in the vinegar sometimes used in canning sardines, the author placed sheets of tin equivalent in size to the interior surface of a can in solutions of varying strength of malic, tartaric, citric, and acetic acids in sealed pint glass jars. The solutions were examined at the end of 3 months, 6 months, and 1 year. One pint of the one-fifteenth normal malic-acid solution in 3 months dissolved 0.0197 gm. tin; the same strength tartaric acid, 0.0246 gm.; and citric acid, 0.0236 gm. It was found in general that the maximum amount of tin was dissolved at the expiration of 3 months. A fifth normal malic-acid solution dissolved 0.0578 gm. tin; a tenth normal solution, 0.0201 gm.; a tenth normal solution of tartaric acid, 0.0382 gm.; of citric acid, 0.0374 gm.; of acetic acid, 0.0019 gm. In 6 months the tenth normal acetic acid had dissolved 0.0083 gm. metallic tin. A method for determining tin in canned goods is described.

Studies on beans, T. KOSUTÁNY (*Landw. Vers. Stat.*, 54 (1900), No. 5-6, pp. 463-479, pl. 1).—The author reports the composition of a number of sorts of beans of French origin and of the same varieties grown in Hungary, together with the weight of the beans, a chemical study of bean oil or fat, and the results of tests of the time required for cooking in distilled water, tap water (river water), and well water, and water to which sodium carbonate or magnesia had been added. As shown by the amount of water absorbed, beans cooked better in distilled water than in tap water or well water. Although the softening of the beans by cooking is influenced by the lime and magnesium content of the water, it is not directly proportional to the lime content. Fresh beans did not cook as readily as older ones. The beans cooked more readily when soda was added to the water, and less readily when magnesia was added.

Remarks on the use of borax and formaldehyde as preservatives of food, W. D. HALLIBURTON (*British Med. Jour.*, 1900, No. 2062, pp. 1, 2; *abs. in British Food Jour.*, 2 (1900), No. 21, p. 244).—In experiments by methods of artificial digestion the author found that 1 part of borax in 1,000 parts of milk completely prevented the curdling action of rennet and even smaller amounts of borax delayed this action. Formaldehyde hindered very markedly the digestibility of fibrin and starch. It appears that soaking two or three days in a 0.5 per cent solution of formaldehyde rendered the artificial gastric digestion of fibrin almost impossible and that even soaking in 0.05 per cent of formaldehyde hindered it very much. Fresh fibrin was digested in 30 minutes by a pepsin solution. When soaked 2 days in a 0.05 per cent formaldehyde solution it was digested in 96 minutes and when soaked in a 0.1 per cent solution or over, it was not digested at all in 24 hours. Formaldehyde, even in small amounts, hindered the pancreatic digestion of starch. The addition of 2 drops of forma-

lin (a 40 per cent solution of formaldehyde) to a fluid ounce of milk greatly delayed the curdling action of rennet. Smaller amounts hindered it less, but in every case the curd formed was less firm than normal.

The relation between temperature and fermentation in the ensiling of green fodders, A. VAUCHEZ, P. MARCHAL, ET AL. (*Ann. Sci. Agron.*, 1900, II, No. 1, pp. 1-32, figs. 5, charts 9).—A record is given of observations on the variations in temperature and in the products of fermentation in silage prepared in different ways. The process of ensiling is defined as the conservation of green fodders by the antiseptic products of their fermentation. The nature, intensity, and duration of the fermentation depend upon the amount of oxygen which gains access to the ensiled material. The main object sought is to prevent as completely as possible the access of oxygen. The three main factors influencing the supply of oxygen in the silo are (1) the character and form of the silo, (2) the method of filling, and (3) the weighting and packing of the silage. The pit silo is recommended because it can be made more nearly air-tight than the above-ground silo. The form of the silo should be as nearly as possible cubical, with rounded corners. In order that the silage may settle uniformly it is recommended that the bottom be made slightly smaller than the top, the incline of the sides being about 5 to 10 cm. per meter. Rapid filling of the silo is not considered advisable, since it is believed that silage of the best quality is obtained by allowing all portions of the mass to undergo the same degree of fermentation. When this condition has been reached the material may be weighted, preferably with soil. Plants in the flowering stage are considered to be in the best condition for ensiling, since more mature, drier plants do not undergo satisfactory fermentation, although this defect may be corrected to some extent by wetting the material as the silo is filled. The method of filling, wetting, and weighting should be varied with the temperature and character of fermentation going on in the silo. A certain degree of fermentation is necessary to the production of the best product. Too great fermentation destroys its value. The best silage is as a rule obtained with temperatures between 55 and 70°. With a temperature over 84° the silage is black and of poor quality.

Excretion of urea by the skin in health, C. C. EASTERBOOK (*Scottish Med. and Surg. Jour.*, 6 (1900), No. 2, pp. 120-140).—Experiments which have to do with the question of the effect of muscular work on the excretion of nitrogen were made, the author himself being the subject. The effect of muscular work and hot baths on the excretion of urea by the skin was studied. Both the work and the baths would each induce profuse perspiration. The composition of the foods making up the uniform diet eaten was calculated and the urine analyzed. The urea in samples of perspiration was also determined.

The author's principal conclusions on the effect of muscular work on the excretion of urea follow:

"When free perspiration was induced the percentage of urea in the sweat rose and remained high as long as the perspiration continued. This was most marked when perspiration was induced by those forms of exercise which involved the free use of the bulk of the muscles of the body, *e. g.*, bicycling and dancing and running. In my opinion this rise in the urea of the sweat of exercise is the direct proof of an increase in proteid metabolism during exercise. . . . During active exercise on a fixed diet the urinary urea gives variable readings according apparently to the degree of concomitant perspiration. The cutaneous urea is always increased; the urinary urea may also be increased, it is more often unaffected, and sometimes it is decreased, but only when sweating has been profuse, and so has carried off an extra amount of urea from the body. For a day or two after active exercise the urinary urea may rise. This rise may be due to a continuance of the excretion of the additional urea in the system, and to a persistence for a longer or shorter time of the stimulating effect of exercise upon the bioplasm of the body. . . .

"The reason why the skin excretes more urea than usual during exercise is probably because it and the lungs are for the time being the naturally predominating organs of elimination. The most obvious accompaniments of muscular exercise are an increased respiration and perspiration. During the perspiration of exercise the skin discharges (1) more water, which by its evaporation serves to carry off most of the additional heat which is being liberated within the body as the result of the increased oxidations; (2) more carbonic acid, and (3) more urea, which is determined toward those organs of excretion which are predominantly active at the time, and so is discharged in relatively larger quantity by the sweat glands, and in relatively less amount by the kidneys."

Milk and artificial foods for fattening calves, D. DICKSON and L. MALPEAUX (*Ann. Agron.*, 26 (1900), No. 5, pp. 217-245, figs. 4).—Experiments are reported on the comparative value for fattening calves of whole milk; skim milk and potato starch; skim milk, starch, and a decoction of flaxseed; skim milk and rice flour; skim milk, rice flour, and a decoction of flaxseed; whole milk with water and barley meal or flour added; skim milk and malt flour; skim milk and artificial cream (an emulsion of peanut oil, sugar and some other substance); skim milk and oleomargarine; and, hay tea and flour. Among the conclusions reached were the following: As regards the quantity of flesh produced and the quality of the meat, the best results were always obtained in fattening calves with pure rich milk. Of the different substances used in combination with skim milk, the best results were obtained with the malt preparations. A decoction of flaxseed with flour or rice starch gave meat of a superior quality. Malt flour cooked with skim milk constituted an economical food and gave very good results. Oleomargarine and sugar may be used with skim milk in the same way as starch and rice flour. Rationally employed it gave very good results, but the quality of the meat produced was not of the best.

Feeding trials with work horses, J. H. SHEPPERD (*North Dakota Sta. Bul.* 45, pp. 577-587).—Timothy hay and brome grass supplemented by oats were compared with horses performing the same

amount of work. It was found that in 42 days there was an average daily gain in weight of 0.42 lb. on the first ration and 0.77 lb. on the second. In studying the comparative value of barley and oats, the former grain was fed for 9 months to 3 horses and 2 mules, timothy hay being supplied in addition to the grain. The mules did not eat the barley with marked relish at any time although during the first 2 months, while at light work, they consumed a sufficient amount to keep them in good condition. When the work was increased, they could not be induced to eat a correspondingly increased amount of barley and frequently refused it altogether. An oat ration was then given them on alternate months. The oats were eaten with apparent relish and on this food gains in weight were made. Two work horses were fed alternately oats and barley, supplemented by timothy hay in 28 day periods for 252 days. On an average there was a daily gain of 0.38 lb. on oats and a loss of 0.15 lb. on barley. When malted barley was compared with oats (the grains being supplemented by oat hay) in a test with 4 work horses, there was an average daily gain in a 49 day period of 0.49 lb. on oats, while on malted barley there was a loss of 0.76 lb. A mixture of malt and bran, 2 : 1, was then compared with oats with the same horses. The test covered two periods of 4 weeks each. Oat hay was supplied for coarse fodder. On the oat ration there was an average daily gain of 0.22 lb. and on the malted barley and bran ration a loss of 0.80 lb. In this and other tests the amount of work done by the different horses was the same. Corn and oats were compared with 2 mules for 84 days, one receiving a ration of oats and corn, the other, of oats alone. Ear corn was used and little or none of the cobs was eaten. The rations were so alternated that the author believes the effects of individuality were counterbalanced. On the corn and oats there was an average daily gain per mule of 0.70 lb. and on the oats a loss of 0.60 lb. Tests from a previous bulletin are reprinted for purposes of comparison (E. S. R., 7, p. 801).

The author's principal conclusions follow:

"Brome hay gave as good results when fed to work horses as did timothy hay. Barley was not equal to oats in feeding value per pound, but was nearly as good. Mules did not relish barley. Malted barley was not so valuable for work horses as oats and was not equal in value to the dry barley from which it came. Corn fed in connection with oats in the proportion of 100 lbs. of corn to 125 lbs. of oats, had greater value than oats; 77.5 lbs. of corn equaled 100 lbs. of oats when fed to work horses."

Cereal breakfast foods, A. P. BRYANT (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 8, pp. 451-453).—A discussion of the food value of different classes of cereal breakfast foods as compared with other common food stuffs.

The Schweitzer system of bread making in Paris, W. P. ATWELL (*U. S. Consular Rpts.*, 62 (1900), No. 234, pp. 307-309).—A special process of cleaning wheat, of grinding it, and of bread making is described. A peculiarity of this process is that the grain is ground only as needed. The cleaned wheat "passes into the mill com-

posed of flat, circular steel grinders, grooved in such a manner that they accomplish the decortication of the kernel and its granulation into meal at the same time. These grinders are movable but do not touch, so that instead of crushing the wheat and producing a flour in which the starch only is retained, the outer and harder portion of the wheat, containing gluten and other nutritive properties, is retained in the flour. The bran alone is expelled." The bread is made almost entirely by machinery.

Banana flour (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 8, p. 466).—A brief note on the value of banana flour.

On an apocynaceous plant yielding large edible tubers, R. T. BAKER (*Proc. Linn. Soc. New South Wales*, 24 (1899), pt. 3, No. 95, pp. 385-389, pls. 2, fig. 1).—A description is given of *Parsonia paddisoni*, a glabrous woody climber, producing edible tubers, and an analysis of the tubers reported. These are known in Australia as "native yams" and are eaten by both colonists and aborigines. In taste, both raw and cooked, they are said to resemble turnips.

The nutritive value of desiccated vegetables, M. E. JAFFA (*California Sta. Rpt.* 1898, pp. 154-157).—The composition of samples of different sorts of evaporated potatoes and a sample of evaporated carrots, is reported. The author discusses the food value of this class of goods, and compares the California evaporated potatoes with the products of Eastern manufacture.

Examination of canned fruits, G. E. COLBY (*California Sta. Rpt.* 1898, pp. 157-159).—The amount of cane fruit and grape sugar in samples of canned apricots is reported.

Investigations of canned products, E. W. HILGARD and G. E. COLBY (*California Sta. Rpt.* 1898, pp. 159-164, dgm. 1).—An examination of spoiled canned asparagus showed that those cans which were not what is technically known as "swells" owed their high acidity to the fluid used in soldering the cans. Zinc and lead were also found, the former being present in the fluid used in soldering and the latter dissolved by the acid present. Experiments were made on the influence of heating upon the liquor of canned asparagus, containing various amounts of soldering fluid. On prolonged heating the acidity of the canned contents increased materially. "This is doubtless to be accounted for by the transformation of the characteristic crystallizable ingredient of asparagus, asparagin, into aspartic acid, by the action of the zinc chlorid [of the soldering fluid]." Analyses show that a not inconsiderable amount of tin accompanied the zinc and usually traces of lead salts. Tests are also reported on the comparative effect of dilute hydrochloric acid upon sheet tin of two kinds. The authors recommend improvements in methods of soldering cans and point out the need of sufficient sterilization.

Poisonous effects of eating meat, P. B. RASMUSSEN (*Maanedsskr. Dyrleger*, 12 (1900), No. 9, pp. 329-364).—This article contains a report on investigations of a large number of cases of poisoning which occurred in consequence of eating fresh meat or meat in the form of sausage and other preparations. The author discusses the pathological changes in the meat of animals affected with various diseases, and the dangers of using such meat for food. Among the diseases thus considered may be mentioned various fever conditions, septicemia, and osteomyelitis. Brief notes are given on the bacteria which were found associated with poisonous meats.

The relation of ethyl alcohol to the nutrition of the animal body, W. S. HALL (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 8, pp. 453-461).—This abstract of a paper presented at the fifty-first annual meeting of the American Medical Association, held at Atlantic City, N. J., June, 1900, is reprinted from the *Journal of the American Medical Association*. A controversial article.

Influence of alcohol on the lacteal secretion (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 7, pp. 405, 406).—A summary of some recent work.

Respiration experiments with a corpulent subject, A. SCHATTENFROH (*Arch. Hyg.*, 38 (1900), No. 2, pp. 93-113, figs. 2).—The respiratory quotient was determined under a number of conditions of work and rest.

Man's power of accommodation to high and low temperatures, M. RUBNER (*Arch. Hyg.*, 38 (1900), No. 2, pp. 120-147).—A study of the effect of climate on man. The respiratory quotient was determined, and in some cases the excretion of nitrogen in the urine. The effect of alcohol on carbon dioxide and water excretion at high and low temperatures was also studied.

Comparative experiments on the activity of the skin of Europeans and negroes, together with observations on diet in warm climates, M. RUBNER (*Arch. Hyg.*, 38 (1900), No. 2, pp. 148-159).—Respiration experiments, in which the production of carbon dioxide and water was measured, are reported with a negro and a European. On the basis of these experiments and theoretical considerations deductions are drawn regarding the kind and amount of food required in the Tropics.

Contribution to our knowledge of proteid metabolism in children, F. W. TUNNECLIFFE and O. ROSENHEIM (*British Med. Jour.*, 1900, No. 2076, pp. 1083-1088, *dgms.* 3).—A comparison as part of a simple mixed diet for young children was made of milk, meat, and "plasmon," a food product prepared from the precipitated casein of milk. The balance of income and outgo of nitrogen was determined, and in one case that of phosphorus. Food, urine, and feces were analyzed. The principal conclusions follow: Plasmon can replace meat in a mixed diet for children in proportion to its nitrogen content. The phosphorus of plasmon can be assimilated and retained. Greater gains in weight were made during the plasmon period than during the meat period in the three experiments reported.

The sweet potato (*Ipomæa batatas*), L. BONNIN (*Rev. Cult. Coloniales*, 7 (1900), No. 66, pp. 709-711).—A note on the feeding value of the sweet potato. Chemical analyses of sweet-potato flour and other products with their nutritive ratios are given.

Investigation of California cattle foods, M. E. JAFFA (*California Sta. Rpt.* 1898, pp. 131-136).—The composition is reported of sugar-beet leaves, crowns and tops, foxtail hay (*Eriogonum parvifolium*), corn meal, wheat bran, wheat middlings, shorts, mixed feed, rolled barley, rice hulls, rice, and pine nuts, as well as the protein content of dried blood, bean meal, and macaroni flour.

Glycogen formation after inulin feeding, R. NAKASEKO (*Amer. Jour. Physiol.*, 4 (1900), No. 5, pp. 246-250).—According to the author's experiments and those of other investigators which he cites, "the glycogen-forming properties of inulin, in the case of the rabbit at least, must still be regarded as uncertain or minimal."

The behavior of certain artificial hexoses, A. MÜNCH (*Ztschr. Physiol. Chem.*, 29 (1900), No. 6, pp. 493-516).—Experiments with rabbits and dogs showed that formose, methose, and methyl glycosid served to induce a storage of glycogen in the liver.

The source of fat in the animal organism (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 9, pp. 529, 530).—The possibility of the formation from fat of protein is discussed.

Can unsaponified fat be resorbed? L. HOFBAUER (*Arch. Physiol.* [*Pflüger*], 81 (1900), No. 4-5, pp. 263-266).—Experiments with dogs fed fat, artificially colored, led the author to conclude that unsaponified fat can be resorbed in the intestine.

On the resorption of artificially colored fat, E. PFLÜGER (*Arch. Physiol.* [*Pflüger*], 81 (1900), No. 8-9, pp. 375-380).—A controversial article. The author believes that Hofbauer's deductions are not warranted by the experimental evidence.

The influence of food and fasting upon animal heat (*Dietet. and Hyg. Gaz.*, 16 (1900), No. 8, pp. 463, 464).—A general discussion of the subject with a citation of some of Mosso's experiments.

Concerning some quantitative relations in digestion by pepsin, E. SCHÜTZ and HUPPERT (*Arch. Physiol. [Pflüger]*, 80 (1900), No. 8-10, pp. 470-526).—An experimental study of the physiology of digestion, with special reference to quantitative results.

Feeding rice meal to pigs, C. M. CONNER (*South Carolina Sta. Bul.* 55, pp. 7).—Corn meal and rice meal were compared with two lots of 3 Berkshire pigs each, the grain ration being supplemented by skim milk. The pigs weighed about 90 lbs. each at the beginning of the test, which covered two periods of 29 and 32 days, respectively. The rations were reversed in the second period. Considering the results of the whole test, the average daily gain per pig on the ration containing rice meal was 1.72 lbs.; on corn meal, 1.66 lbs.; the cost of a pound of gain in the two cases being, respectively, 3.84 cts. and 4.63 cts. A pound of gain required 2.48 lbs. rice meal and 9.91 lbs. skim milk as compared with 2.57 lbs. of corn meal and 10.28 lbs. milk. According to the author rice meal when fed with skim milk has a value equal to corn meal.

Special instruction in poultry culture, A. A. BRIGHAM (*Rhode Island Sta. Bul.* 72, pp. 21-36, pls. 9).—The special course of instruction on the care and management of poultry which the station offers is described.

Heredity, A. A. BRIGHAM (*Rhode Island Sta. Rpt.* 1900, pp. 337-346).—A popular discussion with special reference to poultry.

DAIRY FARMING—DAIRYING.

Feeding experiments, H. J. WING (*Georgia Sta. Bul.* 49, pp. 207-227).—The station has conducted experiments for several years to ascertain the cost of milk and butter production. The average production of 9 cows for one year was 5,610.7 lbs. of milk and 278.6 lbs. of butter. Records of individual cows are given. Four cows produced milk at an average cost of 5 cts. per gallon and butter at an average cost of $12\frac{1}{2}$ cts. per pound. The average cost of food for the 4 cows per year was \$41.28 and the profit in milk was \$47.26 and in butter \$46.29. Two other cows produced milk at a cost of 3.7 cts. per gallon and butter at a cost of 8.37 cts. per pound. Shredded corn-stalks was fed with bran and cotton-seed meal to one cow for one year. The cost of food was \$32.25, and the profit in milk \$39.01 and in butter \$43.43. The comparative value of cotton-seed hulls and pea-vine hay was tested with 2 cows during a period of 2 years. The nutritive ratios of the 2 rations were, respectively, 1:5.40 and 1:5.04. The results were in favor of the cotton-hull ration, the profits being \$9.26 greater per annum. "If the experiment serves no other purpose it shows the wastefulness of feeding an unbalanced ration."

The author discusses briefly the following topics: Georgia as a dairy State, dairying the foundation of diversified farming, cotton v. dairy farming, creameries, the future prospects of dairying in Georgia, and selection of a dairy herd.

Milk examination and milk control, O. BACH (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 3 (1900), No. 12, pp. 819-824).—Seventy samples of the milk supply of Mentz were examined for filth. The range per

liter of milk was from 3 to 42 mg., the majority of samples containing about 10 mg. of foreign matter. The bacteriological examination was equally unfavorable, it being "impossible to count the colonies on the plate cultures."

An apparatus devised by the author for determining the filth in milk is described and figured. This consists of a long cylinder, terminating in a narrow outlet tube at the bottom, which is connected by a rubber stopper with a test tube containing 2 or 3 cc. of water. The cylinder has two side tubes, one near the bottom and the other near the middle, each provided with rubber tubes closed with pinchcocks. The cylinder is closed at the upper end with a glass stopper. After the milk has stood 4 or 5 hours in the cylinder the upper part, including the cream, is drawn off through the middle side tube and the remainder through the lower one. The dirt collects in the test tube, only a small fraction remaining on the shoulder of the cylinder. The latter can be washed out into a beaker after removing the test tube. The dirt is collected on a weighed filter, washed with water, alcohol, and ether, and dried. The addition of a little concentrated ammonia to the milk aids the separation of the dirt. The author finds the apparatus gives more accurate results than any other he has tested.

Experiments with artificial cultures in making export butter, M. GRIMM (*Selsk. Khov. i Lysov.*, 196 (1900), Mar., pp. 565-581).—The author made experiments in ripening cream with pure cultures of *Bacillus acidi lactici* (Hueppe), the cultures of Severin (director of the bacteriological agronomical laboratory in Moscow), Hansen, Tvede, Blauenfeld, and Weigmann, and also with a culture of his own. The latter consists of a mixture of pure cultures of the following microorganisms: (1) A lactic-acid bacillus isolated from spontaneously soured milk and cream, resembling the *Bacterium lactis acidi* of Leichmann, (2) a coccus, and (3) a yeast.

The results of the experiments are stated as follows:

(1) The pure cultures of *Bacillus acidi lactici* (Hueppe) were found absolutely unfit for ripening export butter (Holstein butter). The taste of the butter was disagreeable, there was no aroma, and the acidity was high.

(2) The cultures of Severin gave a good butter with satisfactory keeping qualities, although the aroma was faint when pasteurized cream was used.

(3) The cultures of Tvede gave a butter with an agreeable, well-defined aroma, but not always of satisfactory keeping qualities.

(4) The cultures of Weigmann gave butter with an excellent aroma, but its keeping qualities were poor, although its density was normal. The number of bacteria producing the aroma exceeds that of the lactic-acid bacteria, the former preventing the full development of the latter.

(5) The cultures of Hansen gave excellent results in all respects.

(6) The author's culture gave butter with good flavor and aroma in all cases; the density was unsatisfactory in 2 cases (of a total of 6), and 2 samples did not keep well, owing, according to the author, to the fact that too young cultures were taken for the first ripening. In all other cases the keeping qualities were quite satisfactory.—P. FIREMAN.

Gassy curd and cheese, C. E. MARSHALL (*Michigan Sta. Bul.* 183, pp. 193-205, figs. 9).—A study was made of a bacillus resembling *Bacillus coli communis*, isolated from gassy curd. The production of gas in milk inoculated with this germ was very abundant and rapid at 37° C. The gas contained no oxygen. In one determination 99.1 cc. of the gas contained 76.96 cc. of carbon dioxid and 16.96 cc. of hydrogen. The nature of the remaining 5.18 cc. was undetermined. The appearance of cheese made from milk without the use of a starter, with the addition of a starter of the gas-producing bacillus, and with and without the addition of a lactic-acid starter to check the effect of the gas-producing bacillus is illustrated. The bacillus isolated by the author measured from 2 to 5 μ in length and 0.5 μ in diameter. It was frequently observed in short chains and was thought to be nonmotile. It stained with the common aniline stains, but not by Gram's method. The growth of the bacillus in bouillon and milk and on gelatin, agar, potato, oyster plant, parsnips, ruta-baga, sugar beet, onion, carrot, turnip, and red beet is described. The indol reaction was obtained. The optimum temperature was about 37° C. The bacillus was killed by heating to 60° C. for 10 minutes. Subcutaneous or intraperitoneal injections of 1 cc. of a bouillon culture were fatal to guinea pigs.

The bacterial flora of American Cheddar cheese: Its constancy and distribution, J. WEINZIRL (*Centbl. Bakt. u. Par., 1. Abt., 6* (1900), No. 24, pp. 785-791).—Work by the author upon this subject has been previously noted (*E. S. R.*, 11, p. 487). In the present experiment 62 samples of American cheese, 50 of which were Cheddar, were analyzed. These samples were from 8 States and Canada, and fairly represent the cheese belt extending from New York to Dakota. The ages of the known samples ranged from 2 to 450 days. The number of species of bacteria was found to be quite limited, being greatest when the cheeses were freshly made, and diminishing during and after the ripening period. Cheese 3 to 12 months old was frequently found to contain but a single species. Pure cultures of the bacteria were made by the usual method of dilution, and the results are reported in a table. A form which the author designates as *Bacillus lactis acidii* was found present in all samples, presenting an average of 74.2 per cent of the total bacterial content. Next in number was *B. acidii lactici* (Hueppe), with an average of 21.9 per cent, though it was absent in a few samples of very old cheese. These two forms constituted 96.1 per cent of the total bacteria found, and both

produced lactic acid abundantly, but did not digest the casein of milk. Another form of bacillus was of quite frequent occurrence, while a micrococcus was found more rarely. The two latter differ from the former in that they slowly peptonize gelatine, but they belong to the lactic-acid producing group.

Of the remaining bacteria, 5 produced no apparent change in the milk, and their presence in the cheese was regarded as accidental. Only 1 Bacterium, of which only a single colony was isolated, corresponds to Duclaux's *Tyrothrix* forms.

The author concludes that the lactic-acid producing group of bacteria play a most important rôle in the ripening of hard cheese. Their function can not be stated positively, but it is thought likely that they exert considerable influence upon the flavor. *B. acidi lactici* is a gas-producing organism, and when present in small numbers caused no bad effects, but in large numbers it produced the swelling which is highly detrimental to cheese.

The duration of the life of tubercle bacilli in cheese, F. C. HARRISON (*Ann. Agr. Suisse*, 1 (1900), No. 9, pp. 321-326).—In this experiment milk was thoroughly inoculated with solutions of pure cultures of tubercle bacilli. Emmenthaler and Cheddar cheese were made from the milk in the usual way, using 10 liters for each cheese. From the time of manufacture average samples of the cheese were taken weekly. Equal amounts were macerated in sterilized water and guinea pigs were inoculated with the filtrate. The animals were examined weekly and their general appearance and weight noted. After six weeks or longer the animals were tested with tuberculin. In those diseased the temperature sometimes rose above 2° , while in the others it never exceeded 0.5° . After the test the animals were killed and autopsies made, in which the organs were closely examined with the microscope.

With the inoculations from Emmenthaler cheese from time of manufacture up to from 33 to 40 days tuberculosis developed in the guinea pigs. After 40 days from time of manufacture no evil results followed the inoculations, the bacteria in the cheese having evidently lost their virulence. In the Cheddar cheese the germinating power of the bacilli lasted 104 days, but after 111 days they were incapable of conveying the disease to guinea pigs by inoculation.

The author concludes that Emmenthaler cheese may be eaten with safety, as the period of ripening is much longer than the period during which the tubercle bacilli in the cheese are able to reproduce themselves. Cheddar cheese is seldom eaten under four months from time of manufacture, and during that time the tubercle bacilli become innocuous. However, in order to render the cheese absolutely safe, pasteurization of the milk is advisable.

Five samples of soft cheese were bought in the open market of Berne. The ages of these cheeses were unknown, but they were evi-

dently made within the last few days. Three of the samples conveyed tuberculosis to guinea pigs by inoculation and two did not.

Practical dairying, R. J. REDDING (*Georgia Sta. Bul.* 49, pp. 177-205).—The author discusses in a popular manner dairy cows in regard to breed and type, care of cows, stable management, milking, separating and ripening cream, churning, butter making, cheese making, feeding, dehorning, and other topics. Feeding standards and analyses of feeding stuffs are given. The calculation of feeding formulas is discussed and 19 rations for milch cows and 6 for fattening steers are suggested.

A popular discussion of pure milk supply, C. E. MARSHALL (*Michigan Sta. Bul.* 182, pp. 173-191).—The importance of pure milk for city trade and for the manufacture of butter and cheese is pointed out. Observations by the author on the condition of dairies and stables of different types are reported. Bacteriological experiments made to demonstrate the real significance of pure milk and polluted milk are described. Determinations of the germ content of milk drawn under different conditions are given. The cooling of milk, use of preservatives, inspection and care of cows, construction of stables and milking rooms, and various other phases of the subject are considered at length.

Milk inspection in Leipzig (*Sanitarium*, 46 (1901), No. 375, pp. 140-144).—A consular report of the rules and regulations governing the inspection and sale of milk in the city of Leipzig.

Cream testing, C. H. ECKLES (*Rpt. Iowa State Dairy Com.*, 14 (1900), pp. 55-68).—A popular article on the Babcock test for cream, covering the points of sampling, testing, and sources of error.

Churn v. estimated results in butter making, M. A. O'CALLAGHAN (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1135-1138).—In 58 trials with milk averaging 3.88 per cent of butter fat the loss in manipulation was 0.23 per cent. With a ratio of 85 to 100 for calculating the amount of butter made from the butter fat 0.1 per cent too much was obtained over the calculated results by the Gerber test and 2½ per cent too much by the Babcock test.

Are the lactic acid producing or the Tyrothrix forms of bacteria the cause of the ripening and of the aroma of Emmenthaler cheese? L. ADAMETZ (*Milch. Zig.*, 29 (1900), No. 48, pp. 753, 754).—An experiment is described in which 10 cheeses were made with the use of pure cultures of *Bacillus nobilis* and 10 control cheeses without. The cheese was stored several months and was afterwards examined and scored. Those made with the pure cultures were of much superior flavor and aroma.

Dairy laws of California (*Rpt. California State Dairy Bureau*, 3 (1899-1900), pp. 60).—A reprint of statutes relating to the sale of dairy products and the inspection of dairies and dairy cattle.

National and State dairy laws, R. A. PEARSON (*U. S. Dept. Agr., Bureau of Animal Industry Bul.* 26, pp. 110).—This bulletin contains abstracts of National and State dairy laws now in force and the texts of laws enacted since 1898. The principal subjects on which dairy laws have been enacted in the United States and Canada and State standards for dairy products are shown in tables.

VETERINARY SCIENCE AND PRACTICE.

Two new pyogenic micro-organisms, E. KLEIN (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 14-15, pp. 417-419).—*Streptococcus radiatus* was found in the serous exudations of the diseased udder of a cow. This fluid injected into the body cavity of guinea pigs produced a

purulent inflammation within a few days and a local abscess was formed at the point of injection in which the micro-organism was found in short or long chains in small groups or in larger spheres. The organism is readily distinguished from *Streptococcus mastitidis*. *Bacterium diphtherioides* was found in the purulent secretion of the udder of a cow. The udder was affected in only one quarter and the case had been diagnosed as tuberculosis of the udder. The author gives details of the behavior of this micro-organism on different culture media by means of which it is readily distinguished from the bacillus of diphtheria.

The hereditary transmission of tuberculosis, G. CARRIÈRE (*Arch. Méd. Exper. et Anat. Path., Paris, 1. ser., 12 (1900), No. 6, pp. 782-787*).—In order to determine the influences of tubercle toxins upon the constitution of the young of animals, the author conducted a number of experiments in inoculating guinea pigs. Five series of experiments were conducted in which the guinea pigs received the distilled product of cultures of the tubercle bacillus, the residue of the distillation of these cultures, an ether extract of the bodies of the tubercle bacillus, a toluol extract of the bodies of the tubercle bacillus, and a xylol extract of the same structures. The inoculations were given several months before the period of gestation began, and as a result of inoculation the young were born in diminished numbers and either dead or with feeble constitution. The author concludes from these experiments that tubercle toxins influence gestation in lessening the number of the young, in causing the death of the fetus, the premature death of the young, or a weakened constitution. Further experiments with young animals born under these conditions indicated that they are more sensitive to tuberculosis than normal animals.

Tuberculosis and its management, C. E. MARSHALL (*Michigan Sta. Bul. 184, pp. 207-266, figs. 7*).—Fifty specimens of milk secured from different parts of the State were tested for the presence of tubercle bacilli. Of these samples 16 came from cows which had reacted to tuberculin and in only one case was tuberculosis produced in guinea pigs from these samples. The milk of tuberculous cows at the college was frequently submitted to tests with the result that only one sample of tuberculous milk was found. This sample came from a cow which died a few days afterwards of generalized tuberculosis. A post-mortem examination of this animal showed the presence of the disease in the udder. Of 13 tuberculous cows which were tested for the presence of tuberculosis in the udder only one showed signs of the disease in this organ. In order to study the distribution of the tubercle bacillus in milk and its products, the author secured lung tissue from a tuberculous cow and mixed 1 lb. of the juice pressed from this lung with 120 lbs. of milk. This milk was then passed through the separator and subsequently an examination was made of the slime, the skim milk, cream, butter, and buttermilk which were obtained from the milk. The number of tubercle bacilli found in each of these

products is tabulated by the author. All of the products, including the expressed juice and the milk before separation, were used in inoculating guinea pigs, with the result that a virulent type of tuberculosis was produced in every case. Pigs fed with skim milk and buttermilk developed generalized tuberculosis within 6 months. The author believes that the milk of tuberculous cows may contain the tubercle bacillus and that this organism may find its way into all the milk products.

A number of experiments were conducted in feeding to pigs tuberculous meat in the form of glands. About 50 per cent of the pigs fed with such material developed tuberculosis. The author gives a detailed history of tuberculosis in the college herd since 1889, when the animals were first examined. All animals which gave a reaction to tuberculin on more than one occasion were subsequently shown to be tuberculous. The records of the herd show that the disease is seldom or never transmitted directly to offspring but that infection of calves usually occurs after a year or two. The author recommends that milk should be pasteurized by heating momentarily to a temperature of 85° C. or by subjection to a temperature of 68 to 70° C. for 20 minutes. The author's suggested method for managing tuberculosis is essentially that of Professor Bang.

New procedures in vaccination against symptomatic anthrax of cattle by association of an immunizing serum and virus, S. ARLOING (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 5, pp. 319-323).—During experiments on sheep, it was found that an active immunity could be produced by inoculating with a dose of serum, followed by a dose of the fresh virus, but that it was impossible to rely upon analogous results from injections with a mixture of the virus and serum. When experiments along the same line were extended to cattle, it was found that more satisfactory results were obtained by inoculation with the mixtures. A certain amount of resistance was conferred upon cattle by inoculation with 1 cc. of serum mixed with 0.2 cc. virus, or with a mixture of 0.5 cc. serum and 0.2 cc. of virus. It is possible, therefore, to immunize cattle against blackleg by means of inoculation with the serum and virus, either separately or in mixtures.

Immunity to symptomatic anthrax after the injection of a preventive serum and natural virus, either separately or in mixtures, S. ARLOING (*Compt. Rend. Acad. Sci. Paris*, 130 (1900), No. 15, pp. 991-994).—In a previous communication the author demonstrated the fact that blood serum from a strongly immunized cow confers a passive immunity upon sheep. The immunity produced by the injection of serum is of short duration. In the author's experiments it had entirely passed away by the eighth day. The immunity produced by serum may be strengthened and rendered more durable by subsequent inoculations with a lethal dose of fresh virus.

Experiments were tried in the production of immunity by means of injections with mixtures of the blood serum of immunized animals and fresh virus. Ten animals which were treated with different mixtures of these substances are reported upon by the author, and it appears that nine out of this number died when exposed to symptomatic anthrax.

The author concludes from his experiments that it is a comparatively easy matter to produce immunity in sheep by means of the injection of blood serum and later of active virus. No satisfactory results were produced, however, by injections of mixtures of the serum and virus in any proportions which were tried by the author.

The dissolution of the anthrax bacillus, G. MALFITANO (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 4, pp. 295-298).—Degenerative forms of the anthrax bacillus have long been observed in old cultures or in cultures upon unfavorable media. Under such conditions, the anthrax bacillus dissolves rapidly and loses its form. Such dissolution is believed by the author to be a spontaneous process due to the presence of a proteolytic diastase in the cell. Cultures heated for 10 minutes at a temperature of from 55 to 60° C. dissolved more rapidly than those which are maintained at a normal temperature. A number of antiseptic substances, such as corrosive sublimate, formaldehyde, and cyanid of potash, kill the protoplasm of the bacillus, but hinder the action of diastases at the same time. The author believes that a number of unfavorable conditions may result in the same rapid action of the diastase found in the cell of the bacillus and in its consequent dissolution.

Investigations on the influence of the substratum upon the action of disinfectants toward the spores of anthrax bacillus, U. OTSUKI (*Hyg. Rundschau*, 10 (1900), No. 4, pp. 153-174).—Cultures of anthrax bacillus were kept until abundant spore formation began to take place, when the material was brought in contact with the following substances and allowed to dry upon them: Silk threads, wool threads, pigeon feathers, rabbit hair, silk clothing, leather, wood of the fir tree, filter paper, cotton, glass beads, cover glasses, and garrets. The materials thus covered with the spores of anthrax bacillus were then subjected to disinfection by different methods, among which the most important were steam and a 5 per cent solution of carbolic acid. A table is given showing the different lengths of time that spores lived upon the different substances. The results of this study may be stated as follows: The resisting power of anthrax spores depends upon their origin and their age. The spores retain their resisting power unchanged for a long time, if kept dry at a low temperature. The temperature at which spore formation took place has no influence upon the resistance of the spores. The action of the disinfectants depends upon the structure of the materials upon which spores are dried. Spores which are attached to porous substances are

not so easily destroyed as those upon smooth surfaces. For purposes of study the best material on which to dry spores is pure quartz sand.

Notes on roup, H. W. MARSHALL (*Rhode Island Sta. Rpt.* 1900, pp. 233-244).—From diseased chickens 6 forms of bacteria were isolated in pure culture, and an experiment was conducted in attempting to inoculate other chickens by means of these cultures. During this experiment 12 hens were arranged in 6 pairs, and each pair received daily in drinking water a portion of one of the pure cultures. After 6 weeks of this treatment all the chickens remained healthy. The chickens from which the original roup material was taken were affected in the nostrils and eyes, but did not show any diphtheritic membrane in the throat. Both of these chickens subsequently died. Since it was suspected that the roup organism might develop more vigorously on a medium prepared out of chicken meat, the author used a medium known as rooster agar.

In order to determine the extent of natural transmission of roup, 6 pullets and 4 hens were confined with a roup-y hen, and the eyes of the healthy fowls were rubbed daily with the exudate from the sick bird. All fowls were permitted to drink from the same receptacle. During 2 months 2 of the pullets died and 2 others showed slight swellings about the eyes. None of the 4 more vigorous ones became sick. The author made a microscopic examination of roup tissue taken from the eyes and throat of diseased fowls. Besides various bacteria found in this material, a smaller number of rounded, deeply stained bodies were distinguished, and it is suggested that these may prove to be some form of protozoa. An attempt was made to secure pure cultures of this round organism without success.

In order to obtain experimental evidence on the question of the identity of the roup organism with the diphtheria bacillus, a number of fowls were confined and fed daily with bouillon cultures of *Bacillus diphtheria*. After 6 weeks the fowls were killed and found to be free from diphtheria. Later 4 hens were inoculated subcutaneously with virulent cultures of the diphtheria bacillus, but no case of diphtheria was developed in the hens.

The susceptibility of certain species of animals to the organism of hemorrhagic septicæmia of ducks and chickens, A. RABIEAUX (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 7, pp. 156-158).—In ducks and chickens the disease is easily produced by ingestion of cultures or food substances in which the organism is mixed. Death takes place within from 30 to 48 hours without symptoms except diarrhea near the end of the period. In the pigeon death results within about the same length of time after eating cultures of this organism. The rabbit is very susceptible, and contracts the disease either by ingestion of the organism or by inhalation. In the latter case pulmonary lesions appear.

The disease can be transmitted to the guinea pig by ingestion, inhalation, or hypodermic injection. The white rat succumbs after about 30 hours to inoculation of pure cultures of this organism. In the dog the results of an inoculation are less constant. Intravenous inoculations are always fatal within from 30 to 72 hours. Frogs maintained at a temperature of from 25 to 28° C. succumb rapidly to hypodermic or peritoneal inoculations.

The repeated passing of the organism through animals increases its virulence. In the case of the rabbit it was observed that repeated passages through the rabbit increased the virulence of the organism for the rabbit, but did not alter its virulence toward the pigeon to a noticeable degree. Repeated doses of sterile cultures produced an immunity through a hypodermic inoculation in the rabbit and guinea pig.

Tests of various antiseptics, F. T. BIOLETTI (*California Sta. Rpt.* 1898, pp. 170-173).—An analysis was made of a substance called Purifine, for which high claims were made as to its antiseptic power. It was found not to contain chlorin and bromin, as claimed by the manufacturers. Purifine was compared with a number of other antiseptics, such as bittern water, aluminum sulphate, aluminum chlorid, boracic acid, and calcium chlorid. Various quantities of these antiseptics were placed in sterilized flasks containing ordinary beef bouillon, and they were then inoculated with putrefactive bacteria. The slight antiseptic power of Purifine was found to be due largely to the aluminum chlorid which it contained. This substance, however, was found to be far too expensive for practical application.

Sea water, to which aluminum sulphate was added in the proportion of 55 lbs. to 100 gal., was found to be an effective antiseptic in preventing decomposition, when used in the ratio of 18 gal. to 100 gal. of ordinary sea water. A test of an extract of California laurel (*Umbellularia californica*) showed that this substance had no appreciable effect in checking the growth of bacteria.

Alcohol fumes as a disinfectant, W. VON BRUNN (*Centbl. Bakt. u. Par., 1 Abt., 28* (1900), No. 10-11, pp. 309-315, figs. 2).—The author conducted a number of experiments to determine the disinfectant power of alcohol fumes upon anthrax bacillus. The material used in these experiments came from agar cultures from three sources. The anthrax bacillus was dried upon the surface of silk threads and in this condition exposed to the action of fumes from alcohols of different concentration. It was found as a result of these experiments that 10 per cent alcohol has but little effect upon the anthrax bacillus, while a 25 and 50 per cent alcohol gave off fumes which were considerably more active. The best results were obtained from the fumes of a 75 per cent alcohol. When 95 per cent alcohol was used it was found that the fumes had no effect on the anthrax bacillus. These results indicate that alcohol fumes are most effective as disinfectants when mixed

with a certain percentage of water and that when the fumes contain a very small water content, as in the case of a 95 per cent alcohol, the spore membranes of the anthrax bacillus resist the action of these fumes for the reason that not enough water vapor is present to soften them.

Texas fever (*Arch. Wiss. u. Prakt. Thierh.*, 27 (1900), No. 1-2, pp. 41-85).—This article contains a report to the veterinary service of Germany on the nature of Texas fever. A critical review is given of the American and other literature on the subject, and it is stated that further investigations are to be made for the purpose of determining whether Texas fever may be transmitted by the meat of diseased animals.

Cattle ticks and Texas fever, R. J. REDDING (*Georgia Sta. Bul.* 49, pp. 228, 229).—For preventing the development of Texas fever in northern cattle imported into the South, the author recommends the destruction of cattle ticks on southern pastures. It is urged that this can be accomplished by a rotation of crops and by an inspection of southern cattle twice each week. At such inspections the mature ticks can be removed by hand and the infested parts of animals may be rubbed thoroughly with a mixture of 4 lbs. axle grease to 1 lb. of kerosene and other similar mixtures.

Generalized tuberculosis, R. BURGGRAF (*Ztschr. Fleisch u. Milchhyg.*, 11 (1900), No. 3, p. 79).—In one case of tuberculosis in the cow, it was found that a marked lameness which had been noted for some time before death was due to the presence of the tubercle bacillus in the body of one of the dorsal vertebrae.

Fetal tuberculosis, C. SCHROEDER (*Ztschr. Fleisch u. Milchhyg.*, 11 (1900), No. 3, pp. 79, 80).—In the case of a cow which had tubercular lesions in the lungs, liver, spleen, and mammary gland, small tubercles were found in the portal, mediastinal, and bronchial glands and in the spleen of the fetus.

Regulations for the control of tuberculosis in cattle (*Tijdschr. Veeartsenijk. Muandblad*, 28 (1900), No. 3, pp. 124-135).—A detailed statement of government regulations concerning methods for preventing the spread of this disease.

A simple method of holding the thermometer during tuberculin tests, FRANK (*Deut. Thierärztl. Wchnschr.*, 8 (1900), No. 48, pp. 431, 432).—According to this method of keeping a thermometer in place, a single stitch is taken in the animal tissue, which is said to require but little time and to hold the thermometer firmly.

The technique of taking the temperature during tuberculin tests in large herds of cattle, GRUNDMANN (*Deut. Thierärztl. Wchnschr.*, 8 (1900), No. 48, pp. 429-431, figs. 4).—This article contains brief notes on the various factors which are concerned in giving reliable or unreliable results from tuberculin inoculations, and reports the results of the use of various mechanical devices for holding the thermometer in place.

Tuberculosis in horses, H. MARKUS (*Tijdschr. Veeartsenijk. Muandblad*, 28 (1900), No. 3, pp. 97-113).—The author gives a detailed description of the clinical symptoms and results of post-mortem examination and microscopical study of two cases of tuberculosis in horses. The temperature was somewhat elevated, reaching as high as 40.4° C. A number of tubercles were found in the spleen, the liver was somewhat enlarged, and the mesenteric and lumbar glands were affected. No gangrenous abscesses were found in the lungs. The tubercle bacillus was found in all pathological lesions. The evidence obtained from a study of these cases indicates that the focus of infection was located in the alimentary tract or its appendages.

Tuberculosis in pigs (*Jour. Agr. and Ind., South Australia*, 4 (1900), No. 4, pp. 345, 346).—A butcher purchased 11 pigs and fed them upon the offal from slaughtered cattle and sheep. Of these 11, 9 died after about 4 months, and the other 2 were diseased at the time of examination. An examination of these pigs showed the

presence of well marked tubercular nodules as large as pigeons' eggs in the lungs, and tubercles of various sizes in the liver. The lymphatic glands were also attacked. A bacteriological study of these tubercles determined the presence of the tubercle bacillus.

Experimental tubercular mammitis in the guinea pig, L. NATTAN-LARRIER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 37, p. 1024).—By direct injection of the fluid containing the tubercle bacillus into the mammary gland of the guinea pig, it was found that a local tubercular abscess was produced within a short time. Indurated tuberculosis developed in the glands within from 4 to 5 days, and at the end of 2 weeks a true abscess was formed of considerable size. The experiments indicated that the mammary gland of the guinea pig, like that of domestic cows, is especially susceptible to this disease.

The influence of an inoculation of virulent tubercle bacilli in the dog upon the agglutinating power as determined by a previous inoculation of attenuated bacilli, S. ARLOING and P. COURMONT (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 37, pp. 1025, 1026).—The authors had previously noted that the serum of tuberculous animals in the last stages of the disease was often deprived of an agglutinating power toward the tubercle bacillus. Further experiments were conducted for the purpose of determining the cause of this phenomenon. During the study it was found that virulent bacilli injected into animals which were free from tuberculosis did not cause the appearance or increase of the agglutinating power, as was the case in inoculations with attenuated bacilli. Inoculations with attenuated tubercle bacillus in a dog produced a considerable increase of the agglutinating power and conferred upon this animal a certain resistance to subsequent inoculations with virulent bacilli. Virulent bacilli inoculated into dogs which had previously received attenuated bacilli caused a slight decrease in the agglutinating power.

Liver disease in calves, D. HUTCHEON (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 10, pp. 602-605).—The author reports a number of observations on this disease which indicate that it may be carried from farm to farm by affected calves. The disease appears to be of a contagious nature, but the pathogenic organism has not been isolated. Post-mortem examinations of calves dead of this disease show a congestion of the mesenteric blood vessels and a striking paleness of the muscular tissue, which emits a characteristic odor.

Kidney spot of calves, K. VAERST (*Arch. Wiss. u. Prakt. Thierh.*, 27 (1900), No. 1-2, pp. 110-126, figs. 12).—The author investigated the nature of certain white spots sometimes found on the kidneys of calves and often considered to be of a pathological nature. Such spots were found by the author to be normal phenomena occurring in about 5 per cent of slaughtered animals. The spots are believed to be due to certain processes in the development of the kidney from an embryonic condition. Experiments with unspotted and spotted kidneys indicated that the taste was not badly affected by the presence of the spots.

Diseases of sucking calves, C. O. JENSEN (*Maanedsskr. Dyrlæger*, 12 (1900), No. 8, pp. 297-306).—The author gives a brief account of the diseases to which young calves are especially susceptible, and classifies them into the three groups—accidental diseases, infectious diseases, and digestive disturbances.

Combating hog cholera, U. DE MIA (*Gior. R. Soc. Accad. Vet. Ital.*, 49 (1900), No. 50, pp. 1179-1183).—The author reports the results of experiments in preventive inoculation against hog cholera. Vaccination according to the method of Perroncito was without harmful effects in any case, and produced favorable results in the immunity of treated animals. Of 21 hogs which were vaccinated in one locality, 1 died, while 19 out of 22 check animals died. In another place, 1 out of 15 vaccinated hogs died, while 6 out of the 19 check animals succumbed to the disease. The average mortality from vaccinated hogs according to the author's experience was 9.67 per 100, while that of untreated hogs was 33.68 per 100.

Protective inoculation against hog cholera, FOTH (*Berlin. Thierärztl. Wchnschr.*, 1900, No. 48, pp. 566-568).—The author reports the results of inoculating 4,909 pigs. The value of Landsberg and Prenzlau vaccines in actual cases of hog cholera is believed to be problematical. No reaction occurred in any of the cases of protective vaccination, and it was observed that hog cholera did not appear among herds which had been previously vaccinated with Susserin.

The sale and purchase of animals affected with contagious diseases, P. BRUNO (*Gior. R. Soc. Accad. Vet. Ital.*, 49 (1900), No. 50, pp. 1187-1190).—The author gives a brief discussion of the extent of traffic in diseased animals, and suggests the desirability of a law regulating this business.

The pathological anatomy of pigeon pox, P. POLOWINKIN (*Arch. Wiss. u. Prakt. Thierh.*, 27 (1900), No. 1-2, pp. 86-109, pl. 1, figs. 9).—This disease has been known by a great variety of names, of which the author prefers *Epithelionna contagiosum*. The results of the author's investigations may be briefly stated as follows: The disease is of a benign nature and is not related to the smallpox of mammals. The swellings which are characteristic of the disease are to be considered as products of degeneration and not as tumors caused by parasitic organisms of animal nature. Micro-organisms are found in these swellings, and the disease may be produced by inoculation of healthy birds with such organisms. The serum of pigeons which have recovered from the disease has the property of agglutinating the pathogenic organism.

TECHNOLOGY.

The manufacture of starch from potatoes and cassava, H. W. WILEY (*U. S. Dept. Agr., Division of Chemistry Bul.* 58, pp. 48, pls. 8, figs. 17).—This bulletin reports observations and data on the manufacture of starch from potatoes in Maine and other parts of the United States, together with descriptions of machinery and processes for the manufacture of starch from potatoes and cassava. The bulletin treats of the amount of potato starch produced, the soil, fertilizers, and methods of culture employed in regions where potatoes are grown for starch making, especially in Aroostook County, Maine, the chemical composition of the potatoes grown, the use of potatoes for alcohol making, the microscopic appearance and the uses of the starch produced; and of cassava as an article of food, microscopic forms of cassava starch, culture of cassava, plans for a cassava or potato starch factory, and present status of the cassava industry in Florida.

The total production of potato starch in the United States in 1899 was 15,500 tons, of which 9,000 tons was made in New Hampshire and Maine (6,000 tons in Aroostook County), 400 tons in New York, and 6,100 tons in Wisconsin and other Western States. The analyses reported show that the starch content of Maine-grown potatoes is not as large as that of potatoes ordinarily used for starch making in Germany and other parts of Europe. This is believed to be due to the fact that potatoes rarely mature naturally in Aroostook County, but the tops are usually killed by blight or frost. As a result the maximum starch is probably not developed.

The composition of American wines, W. D. BIGELOW (*U. S. Dept. Agr., Division of Chemistry Bul.* 59, pp. 76).—This is a com-

pilation of 845 analyses made by the Division of Chemistry, and in various parts of the country, accompanied by statements regarding the interpretation of the analytical results and a description of the best methods now in use for the analysis of wines. Attention is called to the fact "that these analyses are not to be accepted in any way as expressing the quality of the American wines produced to-day by the competent wine makers in wineries conducted in accordance with the latest scientific principles of fermentation and ripening." The compilation is intended to be merely introductory to careful chemical studies of "all the typical American wines and their chief characteristics," which it is proposed to take up at once.

Report on the wines made from grapes grown on alkaline soils of Algeria, L. ROOS, E. ROUSSEAU, and J. DUGAST (*Ann. Sci. Agron.*, 1900, II, Nos. 2, pp. 276-320; 3, pp. 321-337).—The author concludes from an extensive series of observations that vines growing on alkaline soils may produce grapes containing a high percentage of chlorid without showing any symptoms of injury themselves. Different investigators have maintained that 0.2 to 0.35 gm. of sodium chlorid per liter is the maximum content for normal wine, but the author has observed much larger proportions of the chlorid without any accompanying injury to the vines. There was no constant relation between the proportion of chlorids in the wine and in the soil on which the grapes were grown, nor between the chlorin and the other constituents of the wine. The amounts of the various saline substances in the grapes seemed to be determined very largely by the climatic conditions, vigor of growth of the vines, etc. The author is of the opinion that the salts are contained mainly in the seeds.

Wattle barks for tanning, J. H. BARBER (*California Sta. Rpt.* 1898, pp. 227-230).—This article gives measurements of typical trees, tannin content of the bark of stems, branches, and large roots, and practical tanning tests of the bark of tanbark acacias (*A. pycnantha*, *A. decurrens*, and *A. mollissima*), planted at the forestry station at Santa Monica. The results of the tanning determinations are given in the following table:

Determinations of tanning material in black and golden wattles.

	Water in air-dried substance.	Tannin.	
		Air-dried substance.	Water-free substance.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
<i>Acacia decurrens</i> (Black Wattle):			
Bark from main stems	6.53	42.48	45.83
Bark from branches	8.26	36.57	39.98
Bark from large roots	5.28	31.35	33.10
<i>Acacia mollissima</i> (Black Wattle):			
Bark from main stems	7.60	45.98	49.76
Bark from branches	8.02	42.98	46.66
Bark from large roots	7.89	32.37	35.18
<i>Acacia pycnantha</i> (Golden Wattle):			
Bark from main stems	9.32	41.80	46.09
Bark from branches	8.67	38.66	42.34
Bark from large roots	7.10	47.02	50.58

Practical tests of the barks in tanning "light russets" from sheepskins gave the following results: One hundred pounds of air-dried bark of *A. decurrens* tanned 106 lbs. of leather, while the same amounts of *A. mollissima* and *A. pycnantha* bark tanned 112 and 96 lbs., respectively. These results coincide approximately with the relative percentages of tannin found by analysis of the air-dried barks.

Uses of wood pulp (*Special U. S. Consular Rpts.*, 19 (1900, pp. 517).—A series of reports are given on the uses and manufacture of wood pulp in various countries.

The use of grape leaves for imparting special aromas to wines, N. PASSERINI and P. FANTECHI (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 436-440).—A number of experiments are reported in which extracts of grape leaves from well-known varieties were added to the fermenting must of wines in order to ascertain the validity of the claim that the flavor and bouquet of wine could be influenced in such a manner. So far as these experiments go, there seems to be nothing to indicate that the aroma which characterizes certain varieties of Italian wines could be imparted to other wines by the addition of extracts from the leaves.

The influence of temperature, acidity, and density of must on its fermentation by various ferments, G. GELM (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 2, pp. 172-182).

Rational methods of vinegar making and their control, J. BERSCH (*Der rationelle Betrieb der Essig-Fabrication und die Controle derselben*. Vienna, Pesth, Leipzig: A. Hartleben, 1900).

The raw materials of the plant kingdom, J. WIESNER (*Die Rohstoffe des Pflanzenreiches*. Leipzig: W. Engelmann, 1900, ed. 2, rev. and enl., vol. 1, pp. 795, figs. 153).

STATISTICS—MISCELLANEOUS.

Annual Report of California Station, 1898 (*California Sta. Rpt. 1898*, pp. 367).—This contains the organization list of the station; a financial statement for the fiscal year ended June 30, 1898; a report of the director; discussions on preparatory teaching in agricultural colleges, by E. W. Hilgard, and on farmers' institutes, by E. J. Wickson; miscellaneous articles abstracted elsewhere; lists of donations and exchanges; brief abstracts of several bulletins of the station; and reprints of Bulletin 119 of the station on vine pruning (E. S. R., 9, p. 949), of Bulletin 124 of the station on lupines for green manuring (E. S. R., 11, p. 534), and of a station circular on the extermination of weeds (E. S. R., 12, p. 350).

Eighteenth Annual Report of New York State Station, 1899 (*New York State Sta. Rpt. 1899*, pp. 503).—This contains the organization list of the station, a financial statement for the year ended September 30, 1899, a meteorological record noted elsewhere, and reprints of Bulletins 158-173 of the station on the following subjects: Combating the striped beetle on cucumbers (E. S. R., 11, p. 269); the forest tent caterpillar (E. S. R., 11, p. 865); report of analyses of commercial fertilizers for the spring of 1899 (E. S. R., 11, p. 917); treatment for gooseberry mildew (E. S. R., 11, p. 945); leaf scorch of the sugar beet, cherry, cauliflower, and maple (E. S. R., 11, p. 1058); the New York apple-tree canker (E. S. R., 12, p. 59); notes on various plant diseases (E. S. R., 12, p. 55); report of analyses of Paris green and other insecticides (E. S. R., 12, p. 67); commercial feeding stuffs in New York (E. S. R., 12, p. 169); a fruit-disease survey of the Hudson Valley in 1899 (E. S. R., 12, p. 154); director's report for 1899 (E. S. R., 12, p. 198); fertilizing self-sterile grapes (E. S. R., 12, p. 240); common diseases and insects injurious to fruits (E. S. R., 12, p. 271); animal food for poultry (E. S. R., 12, p. 276); the efficiency of a continuous pasteurizer at different temperatures (E. S. R., 12, p. 287), and report of

analyses of commercial fertilizers for the fall of 1899 (E. S. R., 12, p. 226). The detailed analyses of commercial fertilizers are omitted in the reprints of Bulletins 160 and 173.

Nineteenth Annual Report of Ohio Station, 1900 (*Ohio Sta. Rpt. 1900*, pp. XXI').—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1900, and a report of the director reviewing the work of the station during the year, discussing the relation of the station to the agriculture of the State, and giving a list of acknowledgments.

Annual Report of Oregon Station, 1896 (*Oregon Sta. Rpt. 1896*, pp. 16, 17, 19-21, 27, 28).—These pages contain notes on the work and needs of the station and a financial statement for the fiscal year ended June 30, 1896.

Annual Report of Oregon Station, 1898 (*Oregon Sta. Rpt. 1898*, pp. 15-68).—This contains a brief review of station work by the director; a financial statement for the fiscal year ended June 30, 1898; a report of the agriculturist reviewing the work of the year and summarizing the results of experiments reported in previous publications of the station (E. S. R., 9, p. 867; 10, pp. 635, 674, 675, 684, 686); a report of the chemist, noted elsewhere; a report of the entomologist, giving notes on various insects studied during the year; a report of the botanist, giving brief notes on Oregon weeds, plant diseases, native clovers, parasitic fungi, etc.; and a report of the horticulturist outlining the experiments undertaken during the year.

Annual Report of Oregon Station, 1899 (*Oregon Sta. Rpt. 1899*, pp. 13-36).—This includes a report of the director, a financial statement for the fiscal year ended June 30, 1899, and reports of the heads of departments reviewing the different lines of station work, and giving briefly some of the results obtained. The report of the chemist is noted elsewhere.

Annual Report of Oregon Station, 1900 (*Oregon Sta. Rpt. 1900*, pp. 12, 13, 17-32).—This includes a report of the director, a financial statement for the fiscal year ended June 30, 1900, and outlines of station work by the heads of departments. Experiments with sorghum are noted elsewhere.

Thirteenth Annual Report of Rhode Island Station, 1900 (*Rhode Island Sta. Rpt. 1900*, pp. 203-383).—This includes the organization list of the station; a report of the director reviewing the work of the station during the year and giving notes on the annual meeting of the Association of American Agricultural Colleges and Experiment Stations; a list of station publications during the year and notes on the station staff; departmental reports reviewing in detail the different lines of station work and containing articles noted elsewhere in this issue; a financial statement for the fiscal year ended June 30, 1900, and list of donations, exchanges, and of the publications of the station since its organization.

Annual Reports of the Department of Agriculture, 1900 (*U. S. Dept. Agr. Rpts. 1900*, pp. 297).—Executive reports.

Press bulletins (*Ohio Sta. Bul. 120*, pp. 263-274).—This includes reprints of the press bulletins issued during the year which have not already been incorporated in the regular bulletins. Following are the subjects treated: Stomach worms in sheep, a comparison of factory-mixed and home-mixed fertilizers, fall treatment of insect pests, fall plowing *v.* white grubs and wireworms, free distribution of sorghum seed, comparison of varieties of potatoes, the soy bean a substitute for clover, spring treatment of fields where wheat has been destroyed by the Hessian fly, the onion thrips, San José scale, tree and plant diseases, the cankerworm, suggestions to orchardists for destroying the San José scale, and black knot and peach yellows.

Announcement to New Mexico ranchmen and list of bulletins, F. W. SANDERS (*New Mexico Sta. Bul. 36*, pp. 29-32).—Brief statements relating to the equipment and work of the station, a subject list of station publications, and the organization list of the station.

NOTES.

KANSAS COLLEGE AND STATION.—Herbert F. Roberts has been appointed botanist to succeed A. S. Hitchcock, resigned. The legislature has made a total appropriation for two years of \$202,253.40. Of this amount \$20,493.40 is made immediately available, \$5,000 being for the purpose of refitting the old chemical building, recently burned, for a gymnasium, and nearly \$15,000 to cover a deficiency occurring in the fiscal year 1899. Seventy thousand dollars is given for a new physics and chemistry building, and \$10,000 for additions to the library. The farm department receives \$7,000 in 1902 and \$2,000 in 1903, and \$2,000 a year is given for farmers' institutes. These liberal appropriations will place the college in better financial condition than it has ever been before. Last year a bill passed Congress granting to the State of Kansas the abandoned Fort Hays military reservation, located in Ellis County, for the purpose of establishing an experiment station there under the supervision of the State station, and a western branch of the State normal school. The State legislature has accepted the reservation and has appropriated to the college \$3,000 a year for two years for carrying on experimental work. The reservation contains 7,600 acres of land, and represents the different soils and other conditions of western Kansas. It is thought to give "the finest opportunity ever offered for field tests on a large scale that are applicable for the farmers of the entire western half of the State."

MINNESOTA UNIVERSITY AND STATION.—In addition to appropriations for current expenses of the department of agriculture and the substations at Crookston and Grand Rapids, the legislature which has just adjourned appropriated \$25,000 for a new chemical building, \$25,000 for a new veterinary building, \$12,000 for an addition to the women's dormitory, \$7,500 for a building for instruction and experiments in dressing and curing meats, \$3,000 for buildings for swine breeding, \$3,000 for an addition to the blacksmith shop, \$3,000 for improvements in the dairy hall, and \$11,200 for barns and other improvements at the substations at Crookston and Grand Rapids. An annual appropriation of \$2,000 for two years was also made for the introduction of agriculture into the rural schools of the State.

MISSOURI UNIVERSITY AND STATION.—The State legislature has just made the largest appropriation ever given the university, aggregating \$467,400 for the biennial period. It provides \$40,000 for a dairy and live-stock building, and an equal amount for a horticultural building and equipment. A medical building, an engineering building, and a dormitory for girls are also provided for. A chair of dairy husbandry is established, \$1,200 given for student labor on the farm, and \$3,500 to the experiment station toward general maintenance. The legislature also made liberal appropriations for libraries and laboratories, out of which the College of Agriculture will receive its share, making, all told, over \$100,000 for agricultural interests.

MISSOURI FRUIT EXPERIMENT STATION.—The State legislature has appropriated \$26,000 for this station for two years, which includes about \$6,000 for permanent improvements of buildings and grounds and the remainder for salaries, traveling expenses, labor, printing, and material for work.

NEW HAMPSHIRE COLLEGE AND STATION.—Clarence W. Waid has resigned his position as assistant horticulturist to accept a similar position at the Ohio Station,

and Harry F. Hall has been appointed to succeed him. Wm. F. Fiske has resigned the position of assistant entomologist to accept the position of assistant State entomologist in Georgia. The legislature at its last session appropriated \$30,000 for an agricultural building for the college, which will contain lecture rooms, laboratories, and offices for the departments of agriculture and horticulture.

NEW MEXICO STATION.—Herbert B. Holt, of Las Cruces, has been appointed regent in place of P. Moreno.

OKLAHOMA STATION.—The term of W. E. Bolton as member of the board of regents having expired, H. C. R. Brodboll, of Ponca City, has been appointed. The legislature has appropriated \$8,000 for buildings. Of this sum, \$6,500 will be expended in the construction of a barn and farm fences, and the balance for many minor improvements on existing buildings. By a recent decision of the court, a levy of three-tenths mill for the year 1901 and four-tenths mill for the year 1902, estimated to yield \$46,000, is made available for the use of the college. The money will be expended in the construction of an engineering building, and an addition to the library building providing for an assembly hall and quarters for the departments of botany and entomology in the college and station.

SOUTH CAROLINA STATION.—L. A. Sease has been elected a member of the board of trustees, *vice* W. H. Mauldin, deceased.

WASHINGTON COLLEGE AND STATION.—The last legislature appropriated \$60,000 for maintenance, \$1,000 for the purchase of live stock, \$25,000 for building and equipping a chemical laboratory, \$10,000 for an armory, \$1,500 for the library, \$1,000 for greenhouses and insectary, \$4,000 for additions to the central heating plant, \$300 for museum cases, \$1,500 for miscellaneous improvements, \$10,000 for a water system, \$5,000 for a sewer system, a small amount for a ward for contagious diseases in the veterinary hospital, and \$10,000 for the substation at Puyallup, of which \$2,000 is for improvement. W. H. Heileman has resigned as assistant chemist of the station to become a field agent in the Division of Soils of this Department.

WEST VIRGINIA UNIVERSITY AND STATION.—President J. H. Raymond has resigned his position and gone abroad for a time. On his return he will go to Chicago University as associate professor of sociology engaged in university extension work. The last legislature repealed the laws under which the boards of all the State institutions, including the university and experiment station, had been appointed, and passed new laws providing in the case of the latter institutions for the appointment of a board composed of six persons of the party in power and three of the minority. The board of regents resigned after accepting the resignation of President Raymond. The new board is constituted as follows: E. M. Grant, of Morgantown; C. E. Haworth, of Huntington; J. W. Hale, of Princeton; Chas. M. Babb, of Falls; J. R. Trotter, of Buckhannon; D. C. Gallagher, of Charleston; J. B. Finley, of Parkersburg; Chas. D. Oldham, of Moundsville; W. J. W. Cowden, of Wheeling. A new fertilizer law has been passed providing a tonnage tax of 40 cts., and requiring manufacturers to make affidavit as to the source from which materials composing their fertilizers are derived. A San José scale law, which is practically the same as the Ohio law, has also been passed.

PERSONAL MENTION.—The formal presentation of a bronze medal to Dr. S. M. Babcock, by the State of Wisconsin, as a mark of appreciation of his services to dairying in the invention of the milk test which bears his name, occurred March 28, 1901, at a joint session of the State senate and assembly. Governor La Follette presided, and in a brief address paid a graceful tribute to Dr. Babcock's skill as an investigator and his generosity in giving his invention to the country. O. H. Fethers, a member of the committee appointed to select the medal, made the presentation. The medal bears the following inscription: "Recognizing the great value to the people of this State and the whole world of the inventions and discoveries of Prof.

Stephen Moulton Babcock, of the University of Wisconsin, and his unselfish dedication of these inventions to the public service, the State of Wisconsin presents to Professor Babcock this medal." In his response Dr. Babcock attributed the opportunity for carrying on the investigation which led to his discoveries to the wise bounty of the State in establishing and maintaining institutions for research. The principal address was made by ex-Governor W. D. Hoard, who pointed out the important relation existing between science and practice in agriculture, and laid great emphasis upon the value of Dr. Babcock's discovery and its world-wide application and introduction. He compared it to the iron plow, the reaper, and the thrashing machine in marking a distinct step of progress in agricultural advancement. He cited it as a notable instance of the value of research, and urged the encouragement of such work along fundamental lines. "The great necessity of the hour with the farmers of Wisconsin is a better knowledge of the laws which must govern the outcome of their labor. The wisest among them see this, feel it, and in their work as farmers endeavor to be governed by this necessity. The leading thought and purpose of all our citizens then should be to so upbuild, establish, and strengthen the cause of agriculture in Wisconsin that knowledge, skill, training, and broad judgment of the relation of things shall direct the hand that labors."

Prof. F. E. Emery, formerly connected with the North Carolina Station, has been appointed special agent of the Dairy Division, Bureau of Animal Industry, of this Department, to investigate dairy interests in China, Japan, and the Philippines, with reference to increasing the sale of American dairy products in these countries.

John A. Myers, of New York, died from typhoid fever, after a brief illness, April 8, 1901. Dr. Myers was born in West Virginia in 1853. He served successively as tutor in chemistry at Bethany College, professor of chemistry and physics in Butler University, Kentucky University, and in the Mississippi Agricultural and Mechanical College, and was State chemist of Mississippi for six years. In 1888 he was appointed director of the West Virginia Experiment Station, which position he occupied until 1897. He then assumed charge of the propaganda for nitrate of soda, which position he occupied at the time of his death. Dr. Myers was widely known among experiment station workers in this country, and took an active interest in the experiment station movement from its inception.

E. S. Nettleton, agent and expert in connection with the irrigation investigations of this Department, died at Denver April 23, 1901. Colonel Nettleton had been prominently identified with irrigation enterprises for many years and was the author of several works on irrigation problems. A bulletin prepared by him on the Reservoir System of the Cache la Poudre Valley was recently issued by this Department.

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director*.

EDITORIAL DEPARTMENTS.

Chemistry, Dairy Farming, and Dairying—The Editor and H. W. LAWSON.
Meteorology, Fertilizers and Soils (including methods of analysis), and Agricultural Engineering—W. H. BEAL.
Botany and Diseases of Plants—WALTER H. EVANS, Ph. D.
Foods and Animal Production—C. F. LANGWORTHY, Ph. D.
Field Crops—J. I. SCHULTE.
Entomology and Veterinary Science—E. V. WILCOX, Ph. D.
Horticulture—C. B. SMITH.
With the cooperation of the scientific divisions of the Department and the Abstract Committee of the Association of Official Agricultural Chemists.

CONTENTS OF Vol. XII, No. II.

Editorial notes:	Page.
The Hawaii Experiment Station.....	1001
Maxime Cornu, botanist, horticulturist, and agriculturist.....	1002
Recent work in agricultural science.....	1004
Notes.....	1099

SUBJECT LIST OF ABSTRACTS.

CHEMISTRY.

A simple method for determining phosphoric acid by means of molybdic solution, J. Hanamann	1004
The determination of potash by means of perchloric acid for commercial purposes, C. Montanari.....	1004
A method for preparing normal, seminormal, decinormal, etc., sulphuric acid of exact strength, R. K. Meade.....	1005
A very delicate reaction for determining the presence of formaldehyde and of milk sugar in milk, E. Riegler.....	1005
A note on the examination of butter and other fats, A. Beychler	1005
Theine in tea, J. Kochs	1005
The nature and properties of corn oil, H. T. Vulte and Harriet W. Gibson....	1006
A method for determining sesame oil in vegetable and animal oils, Tambon..	1006

BOTANY.

Studies on American grasses, F. Lamson-Scribner and E. D. Merrill	1013
Some ways of seed distribution, F. H. Hillman.....	1014
Exchange seed list No. 5, W. A. Setchell and J. B. Davy.....	1014

	Page.
Alkali studies, V. B. C. Buffum and E. E. Slosson.....	1008
The germination and growth of peas in solutions of fatty acid salts to the exclusion of mineral salts, O. Lövison.....	1009
The toxic action of acids and their sodium salts on lupines, R. H. True	1010
The relation of seedlings of gymnosperms to light and darkness, A. Bergerstein.....	1011
Observations on latex and its functions, J. Parkin	1011
The metabolism of proteids in plants, E. Schulze	1012
The artificial inoculation of beans with pea tubercle bacteria, F. Nobbe and L. Hiltner	1013
Fungi of Florida, H. H. Hume	1015
Cryptogams of Wyoming, A. Nelson	1015

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review, Vol. XXVIII, Nos. 10-12.....	1015
Meteorological observations, C. S. Phelps	1016
Meteorological tables, T. S. Outram.....	1017
Meteorological observations, H. L. Price	1017
Meteorological report for 1899, C. B. Ridgaway.....	1016
Rainfall in the west and east of England in relation to altitude above sea level, W. Marriott.....	1017
Anemometry, C. F. Marvin	1018

WATER—SOILS.

River and artesian waters, R. H. Forbes	1019
A preliminary report on the artesian basins of Wyoming, W. C. Knight.....	1019
Lysimeter experiments in 1899, J. Hanamann.....	1020
The lime compounds of cultivated soils and the determination of assimilable lime in soils, D. Meyer.....	1020
The distribution of alkali in the soil of the experiment farm, E. E. Slosson ..	1021
Soils of Mississippi, W. L. Hutchinson, W. R. Perkins, and E. B. Ferris.....	1022
A study of the agricultural value of the soils of Madagascar, A. Müntz and E. Rousseaux	1022
The composition of some Herzegovinian and Macedonian soils, W. Busch....	1023
The geological agronomic charting of soils as a basis for their general valuation, J. Hazard	1023

FERTILIZERS.

An experiment on soil improvement, C. S. Phelps	1025
Phosphorite and green manuring, A. N. Engelhardt	1024
On the utilization of fluorin gas obtained in the manufacture of superphosphates, C. Elschner.....	1025
Analyses of commercial fertilizers, M. A. Scovell, A. M. Peter, and H. E. Curtis	1026
Report of analyses of commercial fertilizers for the spring and fall of 1900, L. L. Van Slyke and W. H. Andrews.....	1026

FIELD CROPS.

Various conditions affecting the malting quality of barley, J. M. H. Munro and E. S. Beaven.....	1026
Some tests relating to the culture of barley, A. Pagnoul	1028
Results of various culture and fertilizer experiments, H. E. Stockbridge.....	1036

	Page
Field experiments with fertilizers, W. O. Atwater and C. S. Phelps.....	1028
Fertilizer experiments during 1900, C. A. Mooers.....	1029
A three-year rotation of crops with potatoes, rye, and clover, H. J. Wheeler and J. A. Tillinghast	1030
Four-year rotation of crops with Indian corn, potatoes, rye, and clover, H. J. Wheeler and J. A. Tillinghast	1030
Researches on the growth of forage plants, Monvoisin.....	1031
Forage plants, B. C. Buffum and W. H. Fairfield.....	1037
Grains, forage crops, and plants for green manuring, A. J. McClatchie	1031
Grasses and fodder plants on the Potomac flats, C. R. Ball.....	1037
Grass experiments, W. Carruthers and J. A. Voelcker	1031
Memoir on the commercial culture of potatoes, M. P. Lavallée.....	1032
Potatoes, A. J. McClatchie.....	1038
Sugar beets, A. J. McClatchie, R. H. Forbes, and W. W. Skinner.....	1038
Experiments with sugar cane, W. Maxwell.....	1033
Wheat experiments, C. L. Newman.....	1034
Wheat.....	1035
Minnesota No. 163 wheat, W. M. Hays and A. Boss	1039
Experiments with winter wheat, A. M. Soule and P. O. Vanatter.....	1035
Variety tests of wheat, oats, and barley, B. C. Buffum and W. H. Fairfield...	1039
Wheat culture at the agricultural school at La Réole in 1898, 1899, and 1900, P. Herbet.....	1036

HORTICULTURE.

Vegetables, A. J. McClatchie.....	1043
Utilizing the greenhouse in summer, F. W. Rane.....	1039
The cultivation of Zhaïm cucumbers, J. G. Smith.....	1043
The best horse-radish varieties of Europe, and methods of cultivation, D. G. Fairchild	1044
The growing of lettuce with chemical fertilizers, W. Stuart.....	1040
Methods of apple cultivation on light porous soil, R. Goethe and E. Junge ...	1041
The essentials of peach culture, J. H. Hale.....	1041
Winter irrigation of orchards, A. J. McClatchie.....	1042
Report of the horticulturist, H. H. Hume.....	1045
Growing and grafting resistant vines, F. Gillet.....	1042
Fertilizer experiments with nitrate of soda in the red wine district of the Ahr Valley.....	1042

FORESTRY.

Experiments in replanting cut-over pine lands, H. H. Chapman.....	1047
Norway spruce for profit on the plains, H. B. Kempton.....	1047
Eucalypts, A. J. McClatchie	1049
Additional notes on tree measurements, C. E. Hall.....	1048

SEEDS—WEEDS.

Red clover seed, A. J. Pieters	1051
The protein substances of seeds, T. Bokorny.....	1049
The influence of the sun's rays upon the germination of seeds, T. Tammes....	1049
On the germination of tobacco seed, M. Raciborski	1050
Germination of wheat and oats treated for smut	1050
Combating weeds by means of metallic salts, Frank	1050

DISEASES OF PLANTS.

	Page.
Report of the department of botany, A. A. Tyler	1055
A preliminary bulletin on the prevention of smut on oats, E. F. Pernot.....	1052
Diseases of celery, H. H. Hume	1056

EXPERIMENT STATION RECORD.

VOL. XII.

No. 11.

The preliminary operations of the Hawaii Experiment Station have been actively entered upon. Since his arrival Mr. Jared G. Smith, the special agent in charge of the station, has devoted himself primarily to the final steps necessary for securing a site for the station, and familiarizing himself with the general conditions. The station is to occupy a tract of land known as Kewalo-Uki in Makiki Valley on the island of Oahu. The land extends from the Punchbowl, in the suburbs of Honolulu, along the east slope of the volcanic ridge, rising from about 100 feet to nearly 1,400 feet in a distance of 2 miles. The lower slope is densely covered with thickets of lantana, with scattering groups of *Prosopis juliflora* and *Opuntia tuna*; the upper third is covered with a planted forest of Australian Eucalyptus, Acacia, and Grevillea species. A site for the headquarters and residence buildings has been definitely decided upon, and it is expected that considerable progress toward the erection of the buildings will be made by July 1. Contracts have been let for the clearing of other portions of the tract, which will furnish a large amount of fire wood and sufficient fence posts for inclosing the whole tract.

Mr. Smith writes that one of the most important lines of work to be taken up at once is that of providing forage and pasturage, as hay is imported in large quantities from California and retails at from \$27 to \$35 a ton in Honolulu. This work will be preliminary to feeding experiments and other experiments in animal production, to be taken up later. A trial will be made of ensiling the cane tops for use as fodder, as at present the sugar planters dry these tops and burn them, and buy hay from California. Another important line of work will be the establishment of new agricultural crops. The great need appears to be for something which can be grown by men of limited means and for which there is already an established world's market, as the Honolulu market is a limited one and is easily glutted. An effort will be made to find varieties of citrus fruits especially adapted to the locality and which will ripen before the California oranges are ready. All of the oranges and lemons used in the islands are at present imported from California, oranges retailing at 5 cents apiece and lemons at 25 cents a dozen. The pomelo grows well and is of good quality. Limes

thrive better than any other citrus fruits, but even these are not raised in sufficient quantity to supply the local market.

There is a troublesome disease among chickens which is said to render it almost impossible to raise poultry in the islands. Many unsuccessful attempts on a large scale have been made. The practical effect of this is well illustrated by the high price of poultry products. Mr. Smith states that a lot of live fowls from California sold recently at auction for \$1.85 each, and that eggs retail at 60 cents a dozen. A suitable poultry feed appears to be another problem, as at present rice is the only grain obtainable for that purpose.

There are several small industries being started, which the station may be able to assist. One is the raising of pineapples for canning purposes, and another banana drying and the manufacture of banana flour.

The outlook for cooperative experiments on all the islands seems to be good, as the people are taking a great interest in the work. It seems evident that as the station develops abundant opportunity will be offered for it to render valuable service to the agriculture of the islands apart from the questions related to sugar production.

Maxime Cornu, whose death occurred recently at Paris, was eminent as a botanist, horticulturist, and agriculturist, and made important economic contributions in each of these lines. He was born at Orleans, July 16, 1843, and received his doctor's degree in 1872, his thesis being a monograph of the Saprolegniaceæ, for which he was awarded the Desmazieres prize of the French Academy of Science. His earlier work was largely in the study of plant diseases and means for their prevention, and in some of these investigations he was truly a pioneer. He became connected with the Museum of Natural History in 1874, and in 1884 succeeded Decaisne as director of cultures at the Jardin des Plantes. Under his direction the plan of the gardens was entirely changed and its scope enlarged. Special efforts were put forth to make the collections of living plants more complete, and in carrying out this plan many little-known species were introduced from various countries, especially from the French colonies. In 1887 he caused to be established a course in colonial cultures. This was the first well-organized attempt made in Europe to secure the study of economic plants of various colonies, and as an outgrowth of this beginning the French Government established in 1897 a garden or station for colonial studies, with a central station maintained in France and branch stations in the different French colonies.

M. Cornu was a member of many learned societies, official commissions on horticulture and agriculture, and the superior council of agriculture, and was the official representative of his Government at numerous international congresses. At a conference held in Berne in

1881 he succeeded in securing an agreement regarding international commerce and exchange in horticultural products. Outside of France M. Cornu is best known by his investigations in vegetable pathology. He took a prominent part in working out the phylloxera problem in France, and has published observations upon many other plant diseases. He was one of the earliest investigators to determine the relationship between the cedar apple and the rust occurring on pear and apple leaves. His publication on this subject dealt with *Gymnosporangium sabinae* on juniper, and *Rastelia cancellata* on pear leaves. The alternate generation of *Puccinia coronata* on oats and the acedial stage of the fungus on the buckthorn were also pointed out. Among other of his investigations were those on the grape mildew and anthracnose, lettuce mildew, pine-leaf rust, hollyhock rust, onion smut, etc. Most of the publications relating to these investigations were issued before he assumed the directorship, as his studies in plant introduction fully occupied him during recent years.

This issue concludes the twelfth volume of the Record, except the index number, which will be No. 12, as usual. The latter is in course of preparation, and is well under way, but will not be ready for distribution for some little time. In the meantime the new volume will be entered upon. A smaller type has been adopted for this, which will enable a considerably larger number of abstracts to be included in each number without increasing the number of pages. By this means it is hoped that the publication of the abstracts may be kept somewhat more closely up to date.

Good progress has been made in the work on the combined index to the first 12 volumes of the Record. The preliminary work on this is approaching completion. Even with the condensation which has been adopted it includes upward of 100,000 separate entries. The combining of these so as to bring all related references together under suitable general entries, in order to make it a practical working index, together with the final editorial work and proof reading, will probably require several months. Although a laborious and expensive undertaking, it is believed that the product will justify this in furnishing a full subject index to experiment station work since the passage of the Hatch Act, and to a very large proportion of the contemporaneous investigation along lines related to agriculture.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

A simple method for determining phosphoric acid by means of molybdic solution, J. HANAMANN (*Ztschr. Landw. Versuchsw. Oesterr.*, 3 (1900), pp. 53-62; *abs. in Chem. News*, 83 (1901), No. 2145, p. 12).—The author finds that at 40° C. the precipitation can be completed in 10 minutes, even in the presence of solutions containing a considerable quantity of iron, by using a molybdic solution strong in nitric acid. The precipitate filters easily, washes rapidly, and does not adhere to the sides of the beaker. By gently calcining the yellow phosphomolybdate of ammonium at a uniform temperature not above a certain point, a deep blue colored compound of constant composition is obtained, containing, according to Meinecke, 3.94495 P₂O₅. If after calcination the precipitate has not the characteristic deep blue color it should be moistened with ammonia, dried and again calcined.

The molybdate reagent is prepared as follows: One hundred grams molybdate of ammonia is dissolved in 150 cc. of ammonia of 0.91 sp. gr., in the presence of 100 gm. of ammonium nitrate. The solution is poured into a liter of nitric acid, sp. gr. 1.2, boiled, filtered, and kept in a brown bottle in a cool place.

The determination of potash by means of perchloric acid for commercial purposes, C. MONTANARI (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 454-462; *abs. in Chem. Centbl.*, 1901, I, No. 3, p. 203; *Chem. Ztg.*, 25 (1901), No. 20, *Repert.*, p. 68).—The reagent used is prepared as follows: Commercial sodium perchlorate, 100 gm., is shaken with 150 gm. of pure concentrated hydrochloric acid. The solution is filtered through glass wool and the hydrochloric acid evaporated. In this way a moderately concentrated solution of perchloric acid, or of perchloric anhydrid, is obtained. A solution of the potash salts freed from ammonium salts, containing about 0.5 gm. of the potash salts, is acidified with hydrochloric acid, an acidified solution of barium chlorid added, the solution filtered, and the filtrate evaporated to 15 to 20 cc. To this 1 cc. of the perchloric acid solution is added and again evaporated to a sirupy consistency. After cooling, about 20 cc. of 95 per cent alcohol containing 2 per cent by volume of perchloric acid solution is added with stirring. After standing 2 hours

the solution is filtered through a Gooch crucible, washed with alcohol containing perchloric acid until the washings amount to 60 to 70 cc., then with a few cubic centimeters of 90 per cent alcohol. The crucible is dried in the air bath for 20 to 25 minutes at 120 to 130 °C., then washed with hot water, dried, and weighed again. The difference in the two weighings gives the amount of pure potassium perchlorate. From this the potash may be calculated by the factor .3402. The results by this method were found to be, on an average, 0.258 per cent lower than those obtained by the platinum chlorid method.

A method for preparing normal, seminormal, decinormal, etc., sulphuric acid of exact strength, R. K. MEADE (*Jour. Amer. Chem. Soc.*, 23 (1901), No. 1, pp. 12-15).—The method of Hart and Croasdale of making a standard sulphuric acid solution by the use of the electric current was found by the author to be accurate, and needs no checking except against errors of manipulation. By this method the electric current is passed through a solution of copper sulphate. The salt is decomposed, the sulphuric acid separating at the anode and remaining in solution. Very accurate results were obtained in making standard acids of various strengths.

A very delicate reaction for determining the presence of formaldehyde and of milk sugar in milk, E. RIEGLER (*Pharm. Centralhalle*, 40 (1900), pp. 769, 770; *abs. in Chem. Centbl.*, 1901, I, No. 3, p. 206).—In testing milk for formaldehyde, phenylhydrazin and a 10 per cent solution of soda is added to a small portion of the diluted milk. In the presence of even 2 drops of formaldehyde to 100 cc. of milk, a rose color will result. In normal milk no color is produced. In determining the presence of milk sugar, a small amount of sodium acetate is added in addition to phenylhydrazin and 10 per cent soda solution, as in the previous case. A rose color will result in the presence of milk sugar.

A note on the examination of butter and other fats, A. REYCHLER (*Bul. Soc. Chim. Paris*, 3. ser., 25 (1901), No. 2, pp. 142-144).—Comparisons are made between the total volatile and the volatile and soluble fatty acids of butter, cocoanut oil, oleomargarine, neutral lard, and mixtures of the same. These results are presented in a table, and from the ratio of the volatile and soluble acids to the volatile acids a third column is drawn, which may be used to determine the nature of fats containing large amounts of volatile acids.

Theine in tea, J. KOCHS (*Rev. Cult. Coloniales*, 7 (1900), No. 59, p. 494; *abs. in Jour. Soc. Chem. Ind.*, 20 (1901), No. 1, p. 58).—The percentage of theine in the teas examined was as follows: Souchong, 2.83; Flower Pekoe, 4.36; Scented tea, 3.08; Pouchong, 3.44; Congou, 3.83; Oolong, 3.66; Cha Morumby, a Brazilian tea, 3.11. The quality and value of tea does not depend alone upon the composition, but also upon the appearance, aroma, and taste of both the leaf and the infusion.

The nature and properties of corn oil, H. T. VULTE and HARRIET W. GIBSON (*Jour. Amer. Chem. Soc.*, 23 (1901), No. 1, pp. 1-8). The investigation reported endeavors to identify the series of fatty acids contained in maize oil. This oil is made up of a complex mixture of glycerids of the fatty acids, a small percentage of volatile oil, and a larger percentage of unsaponifiable matter. Attention is called to the almost insurmountable difficulties, owing to the lack of a definite scheme of analysis, in obtaining accurate knowledge of the properties of the fatty acids.

The methods employed in the present investigation are given, and in the case of previously known constituents, the results are compared with those of other investigators.

In studying the soluble fatty acids, a portion of the aqueous liquid was heated with alcohol and concentrated sulphuric acid. The characteristic odor of ethyl acetate was produced, indicating the presence of acetic acid. By the silver nitrate test the presence of formic acid as determined by Rokitskiy, was confirmed. Further research is needed to prove the presence or absence of caproic, caprylic, capric, and ricinoleic acids in corn oil. The authors conclude that the present investigation adds to the known constituents of the oil, acetic, hypogaeic, and arachidic acids.

A method for determining sesame oil in vegetable and animal oils, TAMBOUR (*Jour. Pharm. et Chim.*, 6. ser., 13 (1901), pp. 57, 58; *abs. Chem. Centbl.*, 1901, I, No. 7, p. 422). To 15 cc. of the oil there is added 7 to 8 cc. of a reagent composed of 3 to 4 gm. of chemically pure crystallized dextrose in 100 cc. of hydrochloric acid. The mixture is shaken 2 or 3 minutes, heated to boiling, again shaken, and the color noted. In the absence of sesame oil, the mixture remains colorless. In the presence of 1 to 5 per cent of sesame oil, a beautiful rose-red color is produced, with violet streaks turning to a cherry red. Ten per cent of sesame oil gives a red color. The same reaction is obtained with the fatty acids of the sesame oil.

Rock analysis, W. F. HILLEBRAND (*Bul. U. S. Geol. Survey*, No. 176, pp. 114 + XIII, figs. 15).—This is a revised edition of the first part of Bulletin 148 of the Survey, giving descriptions of methods and apparatus used in the laboratory of the Survey for the complete mineral analysis of rocks, minerals, etc.

Recent work in soil analysis, H. G. SÖDERBAUM (*Kgl. Landtbr. Akad. Handl. Tidskr.*, 39 (1900), No. 4, pp. 267-274).

On the citrate-solubility of the phosphoric acid of bone meal, T. METHNER (*Ztschr. Angew. Chem.*, 1901, No. 6, p. 134).—The average solubility of the phosphoric acid of 6 samples of bone meal (22 gm. of the bone is 500 cc. of 2 per cent citric acid) was 95.75 per cent.

The valuation of gas liquor, F. J. R. CARULLA (*Jour. Soc. Chem. Ind.*, 20 (1901), No. 1, pp. 23-25).—A discussion of the use of the hydrometer in determining the ammonia content of this substance.

The ash constituents of some Lakeland leaves, P. Q. KEEGAN (*Nature*, 63 (1901), No. 1634, p. 396).—The percentage of ash and the contents of silica and lime in the ash of the leaves of sycamore, wych elm, rowan, common and copper beech, birch,

and Scots pine at different dates are reported. The relation of the ash content and composition of the ash to the character of the soil on which the trees grew, is briefly discussed.

Potable water, woman's milk and cow's milk, food substances, and medicaments, H. LAJOUX (*L'Eau potable, le lait de femme et le lait de vache, matières alimentaires et médicamenteuses*. Reims: F. Michaud, 1900, pp. 172, figs. 6).—Gives methods of examination of water, milk, wines, butter, and other oils and fats, and for the determination of alkaloids, morphin, caffenin, and theobromin, with analytical data obtained in the examination of such products, in the municipal laboratory of Reims.

A practical method for determining the hardness of water, G. MORPURGO (*Giorn. Farm. Chim.*, 50, pp. 440-445).

The gravimetric determination of fat in milk by means of anhydrous sodium sulphate, O. LE COMTE (*Jour. Pharm. et Chim.*, 6. ser., 13 (1901), No. 2, pp. 58-60).—By this method the water in the sample is absorbed by anhydrous sodium sulphate, 20 gm. sulphate to 10 cc. of milk. From the mixture the fat is extracted with ether and estimated in the usual manner.

The logwood test for alum, J. K. COLWELL and A. E. PARKES (*British Food Jour.*, 2 (1900), No. 24, pp. 346, 347).—In testing baking powders for alum it was found that many made of tartaric acid and sodium bicarbonate gave the blue color with logwood extract. Upon testing the ingredients singly it was found that the reaction was produced with the tartaric acid, those samples containing small quantities of iron and lead responding to the test. Freshly prepared logwood extract made faintly alkaline with ammonium carbonate was sensitive to the presence of lead or iron in 1 part per 1,000,000, while a decided blue color was produced with 1 to 100,000 parts. A number of samples of commercial cream of tartar, pure potassium bisulphate, and calcium phosphate failed to give the reaction.

The blue color was also obtained with copper, zinc, and magnesium salts, although with the latter it was faint and rapidly faded.

Delicate tests for the determination of citric and tartaric acids, G. PARIS (*Ztschr. Untersuch. Nahr. u. Genussm.*, 4 (1901), No. 4, pp. 160-162).—A discussion of methods.

The estimation of gluten in flour, MARION and MANGET (*Ann. Chim. Analyt. et Appl.*, 5 (1900), pp. 249-252; *abs. in Analyst*, 26 (1901), No. 299, pp. 44, 45).—A modification of Fleurent's method (E. S. R., 11, p. 1075).

Note on the estimation of glycerol, J. LEWKOWITSCH (*Analyst*, 26 (1901), No. 299, pp. 35, 36).—An extended test was made of that method of determining glycerol in fermented liquors by which the liquor is treated with sulphuric acid and the glycerol estimated from the pure carbon obtained. The method was found to be wholly unreliable.

The treatment of rancid table oils and fats with soda solution, P. HUTH (*Ztschr. Angew. Chem.*, 1901, No. 7, p. 166).—The author recommends mixing common salt with the soda solution in order to reduce saponification and to remove the saponified matter and clarify the fats and oils.

Investigations on the formation of nitric acid during combustion, M. BERTHELOT (*Ann. Chim. et Phys.*, 7. ser., 21 (1900), pp. 145-201).—This is an account of studies of the formation of nitric acid during the combustion in a calorimeter under different pressures and with mixtures of gases of various forms of carbon, sulphur, iron and zinc, and hydrogen, with a discussion of the results as elucidating the principles involved.

Investigations on the method of Berthier for determining the heats of combustion of solid fuels, U. ANTONY and E. DINOLA (*Gaz. Chim. Ital.*, 30 (1900), II, pp. 218-224).

Chemical and calorimetric investigations of fuel, H. LANGBEIN (*Ztschr. Angew. Chem.*, 1900, pp. 1227-1238, 1259-1272).

The plant alkaloids, J. W. BRÜHL, E. HJELT, and O. ASCHAN (*Die Pflanzen Alkaloide*, Brunswick: Friedrich Vieweg, 1900, pp. 586).

On a small laboratory furnace, A. BRUNO (*Compt. Rend. Acad. Sci. Paris*, 132 (1901), No. 5, pp. 256, 257, fig. 1).—An attachment for a Bunsen burner, by means of which a crucible may be heated to very high temperature, is described.

Report of the chemical department of the State experiment station at Albano, Sweden, 1898-99, C. G. EGGERTZ (*Kgl. Landthbr. Akad. Handl. Tidskr.*, 39 (1900), No. 4, pp. 226-257).—The subjects treated in the report are fertilizer experiments with Klagstorp clay soil and with Martebo marsh soil, potash experiments on sandy soils, and sugar-beet experiments conducted during 1898 and 1899.

BOTANY.

Alkali studies, V, B. C. BUFFUM and E. E. SLOSSON (*Wyoming Sta. Rpt.*, 1900, pp. 16, pls. 5).—In continuation of these studies (E. S. R., 11, p. 1052), the authors report on the effect of alkali on the germination and growth of plants, the rate of absorption of salts from solution, and the evaporation of water from salt solutions and plants. It has been shown that the effect produced by salt solutions is inversely proportional to the osmotic pressure of the salt in solution. This indicates that the effect is a mechanical or physical one, and that the deleterious effects of various salts on plants depends on the osmotic pressure of the alkali salt in the soil rather than upon the physiological action of the different kinds of salts. This of course applies only to the neutral salts, and not to those which have a corrosive effect upon plant tissues. To further elucidate the above statement, experiments were carried on in germination and growth of plants in solutions of sulphates and chlorids of potassium and sodium having the same osmotic pressures. From the previous experiments the effect of sodium sulphate was determined and this was taken as an arbitrary base, the strengths of the other salts being $\frac{1}{2}$, 1, and 2 per cent solutions. These percentages of sodium sulphate in solution represent atmospheric pressures of 2.03, 3.8, and 7.1 atmospheres. Wheat and alfalfa seed were germinated in sand which was given an amount of the different solutions equal to 15 per cent of moisture in the sand. From time to time the water lost by evaporation was replaced with distilled water. The germinations are shown in tabular form, from which it is seen that the effect of the different salts on both wheat and alfalfa was almost identical in each series of salt solutions. There was a regular decrease in the germinations of the seeds as the osmotic pressure increased and there was no apparent difference between the effect of sodium or potassium or between the sulphates and chlorids of the same or different salts. As in the experiments previously published, the effect of the salts in solution is to retard the time of germination. While the total percentage of seeds germinated was about the same for the salt solutions as those germinated with distilled water, the retardation amounted to as much as 5 or 6 days.

Pot experiments were conducted with wheat and alfalfa in which the solutions previously described were used, comparisons being made

with the same plants grown in a normal nutritive solution. All the salts in weaker solutions produced a stimulating effect on the growth of both wheat and alfalfa. The decrease from the effect was quite regular with the increase in osmotic pressure with all the salts except potassium chlorid, which retarded growth much less than the other salts. With osmotic pressure represented by 3.8 atmospheres, potassium chlorid forced alfalfa into bloom earlier than the other pots, and its fertilizing effect was very marked except where the strongest solution was used with alfalfa. With this solution the retarding effect was as great or greater than that of any of the salts of the same concentration.

In order to determine how far the salts were absorbed by the plants, they were analyzed for chlorids and sulphates, and it was found that in case of both potassium and sodium sulphates the more concentrated the solution the greater the amount of salt so taken up by the plant; but in the case of the chlorids the normal amount found in the plant was not increased, but in some cases was actually diminished, by increase in the concentration of the solution.

The evaporation of water from the salt solutions and the plants growing in them was measured and the results are given in a table, which shows the amount of water added to each pot to take the place of that lost by evaporation and to bring it back to the initial weight. The increase in evaporation during June was due to the increased amount of water drawn off by the plants as they rapidly increased in size. Wheat produced more weight of plant in the nutritive solution alone than in any of the salt solutions, and in every case less water was lost by evaporation and transpiration from the salt solutions. On the other hand, alfalfa produced more weight of plant in the weaker salt solutions and more water was lost in these solutions than from the nutritive solution alone. In general, there was greater evaporation from the check pots than from those containing salts.

The germination and growth of peas in solutions of fatty acid salts to the exclusion of mineral salts, O. LÖVISON (*Bot. Centbl.*, 83 (1900), Nos. 1, pp. 1-12; 2, pp. 33-43; 3, pp. 65-75; 4, pp. 97-106; 5, pp. 129-138; 6, pp. 185-195; 7-8, pp. 209-224, figs. 4).—Normal solutions of formic, acetic, and propionic acid were found to penetrate the cells of the seed without causing their immediate destruction. The germination of peas was retarded when subjected to solutions of 77.5 per cent normal formic acid, 66.6 normal acetic acid, or 10 per cent normal propionic acid, the effect of the different solutions being in proportion to the molecular weight of the acids. The solutions were found to retard the growth of plants in about the same way that their germination was affected. The average time that plants survived after

being placed in water cultures of normal solutions was 52 days for formic, 28 days for acetic, and 17 days for propionic acid. The injurious influence of these acids upon the plants was mostly shown by the effect upon the roots. The protoplasm of the cells of the roots becomes granular, while the younger cells are killed outright. It was thought possible to accustom plants to acids by beginning with dilute solutions and increasing the concentration, so that plants may not be injured by full normal strengths. It was found that the plants and vessels require frequent cleansing of fungi and bacteria, as these solutions are good nutrient media for cryptogamic plant growth. A concentration of solutions that will prevent the functions of the cotyledons and thereby reduce the plant to a state of starvation was necessary as preliminary to the nutrition of plants. Pea seedlings were kept for 80 days or more in a normal formic-acid solution. The plants grew and developed normally, although somewhat reduced in size.

The author believes that his experiments show the fallacy of the claim that phosphates, sulphates, and alkalies are necessary for plant nutrition.

The toxic action of acids and their sodium salts on lupines, R. H. TRUE (*Amer. Jour. Sci.*, 4. ser., 9 (1900), No. 51, pp. 183-192). - In previous papers dealing with the toxic action of dissolved salts and their electrolytic dissociation, evidence was presented on the ionization of the molecule on the poisonous properties exerted by these substances on the radicles of *Lupinus albus*. The toxicity of the acids was found to be largely due to the action of hydrogen ions formed in the aqueous solution.

In the present paper the effect of certain series of acids and their salts on the lupine is given, from which it appears that in the inorganic acids there is very free ionization. Practically complete dissociation exists at their death limits for lupines. The sodium salts of these acids, as far as tested, agree in having a low toxic value. As a rule, the organic compounds offer somewhat greater difficulties, the ionization of the molecule being seldom complete at the death limit.

The fatty-acid series was examined, from which it was found that formic acid was distinctly the most toxic member of the group. The sodium salts showed little difference in their action, the formate, propionate, and butyrate giving identical death limits. The acetate was found to be very weak in its poisonous action.

The aromatic series was investigated, and in general these acids showed a considerable variation in their toxic values due to their chemical structure. In general, the anions of organic acids were found to possess relatively slight toxic properties, sometimes so slight as to be neglected, as in the case of acetic and hippuric acids. The sodium ions are but weakly toxic and the anions sometimes relatively ineffective.

The relation of seedlings of gymnosperms to light and darkness, A. BERGERSTEIN (*Ber. Deut. Bot. Gesell.*, 18 (1900), No. 4, pp. 168-184). Detailed reports are given of investigations of more than 100 species of gymnospermous plants to ascertain the effect of light and darkness upon their seedlings. The general conclusions of the author show that the seedlings of gymnosperms, with the exception of *Ginkgo biloba* and *Ephedra* spp., become green even in the absence of light. The rapidity with which the green coloration is taken on varies with the temperature, the best temperature being from 15 to 25° C. The experiments with *Cycas* and *Zamia* showed that these plants even in the most favorable temperatures were unable to develop chlorophyll in their seedlings in the complete absence of light. The author believes that this generalization will apply to the Cycadaceæ. Among many of the conifers, especially the Cupressineæ, chlorophyll is formed under favorable temperature conditions in the absence of light, and with the exception of *Larix* spp., it is formed not only in the cotyledons but also in the hypocotyl. Experiments with *Araucaria* showed that this plant was able to produce chlorophyll in branches developed while the plant was kept in darkness for several weeks, the formation of chlorophyll not being confined to the cotyledonary leaves, as is the case of the other conifers. In many of the Coniferæ, especially in species of *Abies* and *Cedrus*, the embryo contains chlorophyll even in the dormant seeds. In others the seedlings begin to turn green before the seed coat is broken or shortly after the emergence of the radical. Seedlings of conifers grown in the dark have shorter roots and cotyledons, but larger and thicker hypocotyls than similar plants grown in the light. The cells of the hypocotyl of plants grown in darkness are absolutely longer and their diameter less than those grown in the light.

Observations on latex and its functions, J. PARKIN (*Ann. Bot.*, 14 (1900), No. 54, pp. 193-214, pl. 1).—Notes are given on a number of observations on the latex observed in rubber plants, and suggestions as to its origin and functions. These observations were made during an economic study of rubber and caoutchouc plants in Ceylon. The coagulation of the latex is said to be brought about by the proteids contained in it passing from a soluble to an insoluble form. The conditions for this coagulation will depend upon the kind of proteid present. If the proteid is a globulin or an albumin it is collected by heating; if an albuminate, by neutralization. The investigations of a number of different latex-bearing plants showed that in the case of *Hevea brasiliensis* the proteid is an albuminate. In *Castilloa* the proteid belongs probably to the class of albumoses, and in *Hura crepitans* the proteid seems to be largely globulin.

Several specimens of the latex which were pure white when first issuing from the wound rapidly darkened on exposure to the air, due

to the presence of an oxydizing ferment or oxydase. The behavior of different kinds of latex in reference to oxydases is mentioned. As a rule oxydases are more frequently found in immature parts of plants.

Investigations made of the carbohydrates of latex show the presence of sugar and starch. The sugar is believed to come from the surrounding tissues and not originally from the laticiferous tubes. Starch rods were found abundantly in the different parts of the plants, and, from experiments conducted with dead and withered leaves, it is believed that the starch present in the latex has nothing directly to do with carbon assimilation. Different characteristics and properties are noted in the latex of young and old organs of the same plant and of different kinds of plants. The effect of previous wounding on the flow of latex was investigated, and it was found that by repeated woundings the amount collected could be increased as much as seven times. This observation was made with Hevea trees, and is of great practical importance from an economic standpoint. In considering the origin and function of latex, the author believes that its principal function is in all probability as a reserve for water. The hypothesis that latex is present in plants for protective purposes is, in the author's opinion, hardly warranted, as rubber and other plants are subject to fungus diseases and insect attacks to as great extent as many other plants not provided with laticiferous tissues.

The metabolism of proteids in plants, E. SCHULZE (*Ztschr. Physiol. Chem.*, 30 (1900), No. 3-5, pp. 241-312; *Ber. Deut. Bot. Gesell.*, 18 (1900), No. 2, pp. 36-42).—A detailed report is given of a series of experiments upon the metabolism of proteids by germinating seeds of *Pisum sativum*, *Vicia sativa*, *Lupinus luteus*, and *L. albus*, a preliminary account of the investigations having been given in the second publication noted above. In seeds germinated in darkness asparagin, leucin, tyrosin, arginin, histidin, and lysin were found. The amounts of these different substances varied with the seedlings, and with the same seedlings at different times. An increase in asparagin was usually accompanied by a decrease in the others, especially in the content of leucin, tyrosin, and arginin. The proteid compounds which were found to accumulate in the etiolated seedlings varied according to the different kinds of seeds, arginin accumulating in *L. luteus*, while at other times in old etiolated seedlings leucin was present in greater or less degree.

The previous theory of the author that the decomposition of proteids in germinating plants results in the formation of certain amido acid compounds as well as hexose bases through the action of acid or trypsin within the organism is said to be confirmed. The varying amounts of these compounds are attributed to the fact of their being secondary products. The older hypothesis that the proteids in germinating seeds split up into asparagin and carbohydrates the author claims is untenable.

The artificial inoculation of beans with pea tubercle bacteria, F. NOBBE and L. HILTNER (*Centbl. Bakt. u. Par., 2. Abt., 6 (1900), No. 14, pp. 449-457, pl. 1*).—Reciprocal inoculations were made upon beans and peas with bacteria from the tubercles of each, and with bean tubercle bacteria from tubercles grown upon peas, and *vice versa*, the object being to ascertain the effect of the adaptation of the organisms to plants of a different genus than that from which they were originally secured. It was found that if either plant were inoculated with germs from the tubercles of the other some tubercles would be formed, but the organisms seemed to be without the power of nitrogen assimilation. If the inoculation was continued a second season, or through a second or third series of cultures, the bacteria became nearly as efficient as those from the roots of the same genus. To the organisms resulting from such adaptations the authors have given the name "crossed" or "crossbred bacteria." If inoculations with these crossbred bacteria be made upon their original host they will be found to have nearly lost their ability of nitrogen assimilation on the roots of that plant, showing little if any increased nitrogen content over non-inoculated plants. The effect of the various inoculation materials as shown by the experiments with peas is given in the following table:

Average results of inoculating peas grown in pots.

Inoculation material.	Height of plants.	Number of leaves per plant.	Pods per pot.	Seeds per pot.	Dry matter in plant.	Nitrogen in plant.
	<i>Mm.</i>				<i>Gm.</i>	<i>Mg.</i>
Bean tubercle bacteria	888	18	11.5	8.0	5.29	76.5
Pea tubercle bacteria	1,144	19	28.0	108.5	24.03	743.0
Crossbred bacteria	1,146	18	26.0	59.0	16.78	366.0
Check, uninoculated	891	17	7.0	9.0	5.33	89.0

If the dry matter and nitrogen content of beans and peas inoculated with their own root tubercle bacteria be each represented by 100, the effect of crossbred bacteria upon beans would be represented by 80.74 for the dry matter and 74.8 for the nitrogen content. Upon the peas crossbred bacteria produced 69.83 per cent of dry matter and 49.26 per cent of the quantity of the nitrogen stored up in plants inoculated with pure pea tubercle bacteria. The possibility of the transfer of tubercle bacteria from the roots of one plant to those of a different genus is affirmed.

Studies on American grasses, F. LAMSON-Scribner and E. D. MERRILL (*U. S. Dept. Agr., Division of Agrostology Bul. 24, pp. 55, figs. 23*).—Notes are given by the authors on some recent collections of Mexican grasses, of which 227 species and varieties are enumerated, 11 species and 1 variety being new. Notes are also given on some species of *Panicum*, in which Lamarck's types of *P. nitidum*, *P. scoparium*, and *P. pubescens* are figured and described. Miscellaneous notes and descriptions of new species are also given by F. Lamson-Scribner and C. R. Ball of a number of grasses occurring in the Gulf States. Five new species of *Elymus* are figured and described.

The order of formation of the elements of the central cylinder in roots and stems, G. BONNIER (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 20, pp. 781-789, figs. 6).—The general structure of the central cylinder and that of the stem and root and the order of the development of the tissues are the same except in the different position of the ligneous poles.

Some ways of seed distribution, F. H. HILLMAN (*Nevada Sta. Bul.* 48, *Educational Ser.* III, pp. 10, figs. 15).—The author figures and popularly describes some of the methods by which seeds of weeds and other plants are distributed.

Exchange seed list No. 5, W. A. SETCHELL and J. B. DAVY (*California Sta.*, 1900, Dec., pp. 11).—A list is given of seeds of economic plants which are offered for exchange and a list given of seeds which are desired by the department of botany at the station. The seeds enumerated in this list are for exchange only.

New sugar-yielding plant in French Central Africa, A. CHEVALIER (*Sucr. Indig. et Coloniale*, 57 (1901), No. 3, pp. 75-81).—The plant discussed in this article is Bourgon (*Panicum burgui*).

Influence of atmospheric humidity on vegetation, S. MOTTET (*Rev. Hort.*, 73 (1901), No. 2, pp. 38, 39).—The author believes the rôle of atmospheric humidity in plant growth is greater than is usually supposed. Observations on the growth of a number of different plants as influenced by atmospheric humidity are presented.

Reproduction in relation to problems in hybridization, O. AMES (*Amer. Gard.*, 22 (1901), No. 322, p. 130).—A controversial article.

Reserve carbohydrates of Thaliophytes, G. CLAUTRIAT (*Misc. Biol. déd au A. Guard*; abs. in *Jour. Roy. Micros. Soc.* [London], 1900, No. 6, p. 698).—According to the author, the most abundant carbohydrate in the Myxomycetes is glycogen, which usually occurs in the plasmodia in a half-dissolved condition. The spores contain only oily substances. The Peridiniæ contain drops of oil and pure starch, and their membranes give the reaction of cellulose. In the Cyanophyceæ a reaction with iodine is given, resembling that of glycogen, and the presence of glycogen in bacteria is believed probable. In the green algae starch is abundant, and in many of the red algae a carbohydrate closely resembling starch is present. Fungi are said to contain an abundance of glycogen and oily substances, besides various forms of sugar, glucose, levulose, trehalose, and mannite.

The influence of chemical agents on the growth of algæ and fungi, N. ONO (*Jour. Col. Sci. Imp. Univ. Tokyo*, 13 (1900), pp. 141-186, pl. 1; abs. in *Jour. Roy. Micros. Soc.* [London], 1900, No. 6, pp. 698, 699).—A large number of experiments are reported upon, in which the effect of different chemical salts upon algæ and fungi is shown. Extremely dilute solutions of some poisonous salts were found to promote the growth of the lower algæ. Among these were zinc sulphate, iron sulphate, copper sulphate, and iron arsenite. These substances favored the multiplication of the organisms rather than increase in the size of the individual. The fungi were found to be more sensitive to small quantities of mineral salts than the algæ, and the formation of spores was especially checked by these substances. The optimum concentration of mercurial chlorid for fungi was found to be about 0.0013, and of copper sulphate about 0.012.

The meaning of mycorrhiza, E. STAHL (*Jahrb. Wiss. Bot.* [Pringsheim], 34 (1900), pp. 549-668, figs. 2; abs. in *Jour. Roy. Micros. Soc.* [London], 1900, No. 6, p. 707).—The author enumerates all the plants in which ectotropic and endotropic mycorrhiza are known to exist. At present, mycorrhiza are unknown in the families Cruciferae, Cyperaceæ, and Polypodiaceæ; but the author considers it probable that the greater number of the higher plants are capable, under certain circumstances, of entering into symbiosis with fungi. The explanation of the occurrence in the same forest of plants which do and others which do not obtain their nourishment in this way is found in the difference in their facility of absorbing mineral food material. Plants

with a rapid transpiration current can dispense with the formation of mycorrhiza, while those with weak transpiration can obtain a sufficient supply only by the assistance of the symbiotic fungus.

Notes on the cytology of Gastromycetes, R. MAIRE (*Compt. Rend. Acad. Sci. Paris*, 131 (1900), No. 26, pp. 1247, 1248).—Cytological notes are given upon the study of a number of species of Lycoperdon, Nidularia, Geaster, and Cyathus.

Fungi of Florida, H. H. HUME (*Florida Sta. Rpt. 1899 and 1900*, pp. 38-44, fig. 1).—A list is given of fungi collected by the author and others, in which the distribution of the species is indicated and several new species described.

Cryptogams of Wyoming, A. NELSON (*Wyoming Sta. Rpt. 1900*, pp. 38).—A list is given with descriptive notes on a number of species of cryptogams that have been collected by the author and others in the State of Wyoming. This list is published as supplemental to the report on the flora of Wyoming (E. S. R., 8, p. 956).

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review*, 28 (1900), Nos. 10, pp. 425-476, figs. 17, charts 10; 11, pp. 477-526, pls. 2, figs. 4, charts 10; 12, pp. 527-583, pl. 1, fig. 1, charts 10).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts for the months of October, November, and December, 1900, these numbers contain the following articles and notes.

No. 10, special contributions on Lightning from a cloudless sky, by B. S. Pague; Property loss by lightning in the United States, 1899, by A. J. Henry; Cumulus clouds at the Bayonne, N. J., fire, by J. H. Eadie; Drift ice and the theory of ocean currents, by R. A. Daly; The dynamic principle of the circulatory movements in the atmosphere (illus.), by V. Bjerknes; and The Porto Rican hurricane of 1899, by C. O. Paullin; and notes by the editor on the Weather Bureau at the Paris Exposition, the proceedings of the Permanent International Meteorological Committee, oscillations of lake level, correction, Weather Bureau men as instructors in meteorology, training needed to become investigators, climate and flora, heaviest rainfall at La Crosse, Wis., meteorological cablegrams, psychrometric tables, observations during the solar eclipse, pogonip, and the long record of Mr. S. P. Davidson.

No. 11, special contributions on Rainfall from convectional currents (illus.), by H. H. Kimball; Rainfall on the Island of St. Kitts, W. I. (illus.), by W. H. Alexander; Notes on local whirlwinds in New Brunswick, by S. W. Kain; Lightning from a cloudless sky, by C. E. Ashcraft, jr.; Climate of Spokane, Wash., by C. Stewart; Fog studies on Mount Tamalpais, by A. G. McAdie; The water supply for the season of 1900 as depending on snowfall; and Tornadoes in Tennessee, Mississippi, and Arkansas (illus.), by S. C. Emery.

No. 12, special contributions on The circulatory movements in the atmosphere, by V. Bjerknes; Line integrals in the atmosphere (illus.), by F. H. Bigelow; The people of Mars, by C. F. Talman; Prof. N. H. Yerby, by F. P. Chaffee; and Records by the kite corps at Bayonne, N. J., by W. H. Mitchell; and notes by the editor on weather forecasts in Mexico, meteorology in Costa Rica, micro-photographs of snow crystals, bombarding hail clouds, meteorology as a college course, mars and the earth, oscillations of the lakes and the climate in arid regions, erosion due to heavy rains and steep grades, mirage over Lake Michigan, meteorology at the Paris Congress of 1900, meteorology and geodesy, periodicity in meteorology, mathematics in meteorology, a memorable storm of sleet and snow, hurricanes at Charleston, S. C., high

tides and approaching storms, cumulus clouds above fires, lightning without thunder, reduction of the barometer to standard gravity, hurricanes in Jamaica, W. I., commercial importance of storm and weather forecasts, the evolution of the thermometer, a barometer needed in balloon voyages, lectures and instruction, the use of the Monthly Weather Review by teachers, aerial voyages by balloons and kites, transatlantic weather, correlation of weather in distant localities, new meteorological stations needed, lightning from cloudless skies, lake commerce and insurance, the weather and the newspapers, the first National Meteorological Congress of Mexico, chronological cycles, relations between summer and winter temperatures, Arctic and Antarctic meteorological observers, typhoon of November 10 in Hongkong, equinoctial storms, and Weather Bureau publications for school use.

Meteorological observations, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1899, pp. 219-221*).—This is a record of observations on temperature, pressure, humidity, precipitation, cloudiness, and wind movement during each month of 1899 at Storrs, and on rainfall during the 6 months ended October 31, 1899, at 21 places in Connecticut. The mean temperature for the year at Storrs was 47° F.; mean pressure, 30.07 in.; total precipitation, 38.31 in.; number of cloudy days, 102. The average rainfall for the State during the 6 months ended October 31 was 19.34 in.

"The total precipitation for the year (38.31 in.) was 6.8 in. below the average at Storrs for the past 11 years, and about 10 in. below the general average for Connecticut. . . . The last killing frost in the spring occurred May 4. The temperature for June was somewhat above the normal, but for the balance of the summer it was about the average. The growing season was shorter than usual, light frosts occurring September 7 and 14, and quite severe frosts September 15 and 16."

Meteorological report for 1899, C. B. RIDGAWAY (*Wyoming Sta. Rpt. 1900, pp. 23*).—A brief statement of the equipment of the station for meteorological observations, with tables giving daily observations on temperature, relative humidity and dewpoint, atmospheric pressure, and wind movement at Laramie, Wyo., for each month of 1899, as well as a monthly summary of precipitation and evaporation for 1891-1899. The summary for 1899 is as follows:

Temperature (degrees F.).—Highest, 87, June 29 and July 25; lowest, -40 , February 12; mean for the year, 38.8; highest daily range, 63, February 12; lowest daily range, 5, October 9; mean daily range for the year, 24.4. *Humidity*.—Mean relative for the year, 57.1; lowest relative, 6, September 7. *Dewpoint*.—Highest, 60° , September 5; lowest, -38° , February 6; mean for the year, 23.9° . *Atmospheric pressure* (inches).—Highest, 23.502, September 25; lowest, 22.442, January 31; mean for the year, 23.079. *Precipitation* (inches).—Highest monthly, 2.01, in July; lowest monthly, 0.07, in November; highest during any single storm, 0.91, July 13; total for 1899, 11.84; mean for 9 years, 10.15. *Evaporation*.—Total for 6 months (April 22 to October 15), 20.58 in.; greatest monthly, 4.42 in., in May. *Wind*.—Prevailing direction, southwest; greatest velocity, 58 miles per hour; total number of miles traveled during the year, 117,284; greatest number of miles traveled in 1 month, 12,787, in January; lowest number of miles traveled in 1 month, 7,245, in November; average number of miles for each month, 9,773.6; greatest number of miles in 1 day, 744, May 21; least number of miles in 1 day, 97, December 13. *Weather*.—Number of clear days, 178; number of fair days, 142; number of cloudy days, 45; number of days on which there was a precipitation of 0.01 or more, 75.

Rainfall in the west and east of England in relation to altitude above sea level. W. MARRIOTT (*Quart. Jour. Roy. Met. Soc. [London]*, 26 (1900), No. 116, pp. 273-280, figs. 2). The mean monthly and annual rainfall at the English and Welsh stations are grouped according to altitude, all stations being considered as "western" which drain to the west and all "eastern" which drain to the east. There is shown to be a general increase in rainfall as the altitude increases up to 1,000 ft. There is nearly a fourth more rainfall in the west than in the east, but it is much more variable. The greatest rainfall occurs in the west in November, in the east generally in October, although there is a great rise of rainfall both east and west from June to July. April, May, and June are very dry in the west. The greater rainfall of the western part of the British Isles is explained by the fact that the prevailing winds are southwesterly. The author considers the assumption of an increase of 3 per cent for each 100 ft. to be incorrect. It is shown by the data here reported to vary from 1 to 38 per cent, depending upon exposure, position, and surroundings, as well as upon altitude.

The climate of Allegany County, O. L. FASSIG (*Maryland Geological Survey—Allegany County*. Baltimore: Johns Hopkins Press, 1900, pp. 217-231, figs. 5).—Tables and diagrams are given which show the results of temperature observations at Cumberland for 37 years (1859-1895), the mean monthly and annual temperatures for 9 stations in Allegany County at which observations have been made during a period of one year or more, the monthly and annual precipitation at Cumberland during the period from 1871-1895, and the general climatic features of the county are briefly discussed. The highest temperature recorded is 109° F. at Boettcherville July 3, 1898, the lowest -22°, at Frostburg February 13, 1899. The mean annual temperature at Cumberland, based on 37 years' observations, is 51.5°. The mean annual rainfall at the same place, based on 27 years' observations, is 32.86 in. The stations for meteorological observations in the county are described.

Meteorological tables, T. S. OUTRAM (*Minnesota Sta. Rpt. 1900*, pp. 731-739).—Tables prepared by the director of the Minneapolis office of the Weather Bureau are given, showing the monthly and yearly averages and departures from normal of temperature and precipitation, based on observations at some 64 places in Minnesota during the year ended June 30, 1900.

Meteorological observations, H. L. PRICE (*Virginia Sta. Rpt. 1900*, p. 10).—Tables are given which show monthly averages of observations at Blacksburg, Va., on temperature, precipitation, direction of wind, and cloudiness, for the year ended June 30, 1900; and monthly means of temperature and precipitation during 8 years (1893-1900). The mean temperature for the year ended June 30, 1900, was 82.71° F., the precipitation 35.36 in.

Moore's meteorological almanac and weather guide, 1901, W. L. MOORE (*Chicago: Rand, McNally & Co., 1900*, pp. 128, figs. 21, charts 32).—The object of this treatise is stated to be "to present in concise form such weather data and facts relative to meteorological phenomena as will be at once interesting and profitable to the farmer, the horticulturist, the shipper of perishable produce or manufactures, the merchant, the mariner, the teacher, the student, and the seeker after health or pleasure. Effort will be made to correct many popular but erroneous impressions relative to climate and weather." It contains in addition to the usual data given in almanacs,

statements of the highest and lowest temperatures recorded at different places in the United States during each month of the year, and articles relating to the history of meteorology; some wonderful phenomena of the air, the construction and the use of the weather map (with charts), the uses and the errors of storm warnings, tornadoes, long-range forecasts, the Galveston hurricane of 1900 and the blizzard of 1889, great floods of the United States, protection from frost, loss of life and property by lightning, lightning strokes, temperatures injurious to food products, Weather Bureau kites, work of voluntary observers and crop correspondents, magnitude of the United States daily atmospheric survey, and climate for the health seeker, the tourist, and the investor, including information regarding the climate of Cuba, Porto Rico, Hawaiian Islands, and the Philippine Islands; the hottest and coldest places in the world, the weather and sun spots, and change of climate.

The weather and agriculture, R. BÖRNSTEIN (*Deut. Landw. Presse*, 28 (1901), Nos. 5, pp. 31, 32; 7, p. 45).—A general discussion of this subject.

The weather v. the newspapers, H. M. WATTS (*Pop. Sci. Mo.*, 58 (1901), No. 4, pp. 381-392, figs. 4).—The relation of the newspapers to the dissemination of information regarding the weather is briefly discussed, the claim being made that "for the most part the average newspaper fails in its duty to the public, so far as the weather is concerned, in the four following particulars:

"(1) By reason of a misapprehension and misrepresentation of the simplest fundamental facts of atmospheric circulation and weather movement, effects being treated as causes, etc.

"(2) By reason of a constant confusion of terminology and a generally slipshod use of weather terms and facts.

"(3) By reason of a persistent refusal to recognize much, if any, difference between the scientist and the charlatan, between the expert and the quack; and, in fact, by a disposition—marked in some quarters—to give undue prominence to bogus weather prophets and wonder-mongers, at the expense of the equipped and reputable students of the subject.

"(4) By reason of a hypercritical but uninformed attitude toward the daily forecasts of the United States Weather Bureau, by which the work of the Bureau is hampered and its value to the public materially reduced."

Cannonading as a protection against hail, J. DUFOUR (*Chron. Agr. Canton Vaud*, 14 (1901), Nos. 3, pp. 61-62, figs. 2; 4, pp. 95-107, figs. 5).—A brief general discussion.

The mode of action of cannon used in combating hail, G. GASTINE and V. VERMOREL (*Grêle*, 2 (1901), No. 3, pp. 12-18).

Corrections for mean daily temperature calculated from a limited number of observations, M. MORENO Y ANDA (*Mem. y Rev. Soc. Cient. "Antonio Mazaré"*, 15 (1900-1901), No. 1-2, pp. 5-11).

Anemometry, C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Doc. 233*, pp. 67, pl. 1, figs. 28).—This is a second edition, revised, of "a circular of general information respecting the theory and operation of instruments for indicating, measuring, and automatically recording wind movement and direction, with instructions for the erection and care of such instruments of the Weather Bureau pattern."

An electric anemometer for transmitting observations to a distance, E. LEGRAND (*Compt. Rend. Acad. Sci. Paris*, 132 (1901), No. 6, p. 323).

New wind-recording apparatus (*Sci. Amer. Sup.*, 51 (1901), No. 1308, p. 20963).—A brief description of an apparatus in use at the Agricultural College of Berlin which is capable of recording eight directions of the wind.

Meteorological instruments, H. HARTL (*Sci. Amer. Sup.*, 51 (1901), Nos. 1308, pp. 20962, 20963; 1309, pp. 20978-20980, figs. 20).—Descriptions are given of various forms of thermometers and thermographs and barometers, barographs, psychrometers, etc., with brief explanations of their use.

WATER—SOILS.

River and artesian waters, R. H. FORBES (*Arizona Sta. Rpt. 1900*, pp. 180–184).—The results are reported of determinations of silt, alkali salts, and nitrogen in representative samples from a flow of one week, both high and low water, of the Colorado at Yuma, the Gila at Florence, and the Salt River at Mesa City; also of a canal taking water from the lower Gila, as well as of alkali salts in 9 samples of water from artesian wells on the eastern slope of Graham Mountain above Safford, Thatcher, and Pima and in the San Pedro Valley south of Benson. The analyses reported show that the 3 principal rivers of the Territory are “of quite variable character for irrigating purposes, containing, in the instances mentioned, from 50 to 200 parts of soluble salts in 100,000, in round numbers.”

“The quantity of soluble salts is influenced by the stage of water and by seepage from irrigated districts. The nature of these salts is influenced by the same causes. The Colorado River is less saline the year around than either the Salt or the Gila. In summer, when its waters rise under the influence of the melting snows in Colorado and Utah, the total soluble solids were observed to average as low as 25 parts in 100,000 for months at a time.

“Flood waters in all cases not only carry less salts but more silt, including nitrogenous fertilizing materials. Barring the inconvenience of excessively muddy water, therefore, flood waters are in every way preferable for irrigating purposes.

“The average amount of silts in the Salt River supply from August 1, 1899, to August 4, 1900, was by weight 0.1 per cent of the water; by volume, 0.3 per cent. This amount of silt is unquestionably less than the average on account of the unusually low water prevailing during most of the time of sampling. The Salt River, however, is undoubtedly far less silty than the Gila, and this element of doubt in connection with the life of reservoirs correspondingly less. . . .

“The average total nitrogen in the Salt River supply for one year was found to be 3.25 parts in 1,000,000 of water, including that which was contained in the silt. Of this amount 1.04 parts per million existed in the form of nitrates.”

The analyses of the artesian waters show that while the total soluble salts are not excessive, sodium carbonate is uniformly present, varying in different cases from 3.4 to 19.6 parts per hundred thousand. An analysis of an alkali crust from the region in which some of the artesian wells are located shows that a considerable amount of calcium sulphate is present. “Should the soils of this region prove to contain calcium sulphate generally, the alkalinity of the artesian wells will, at least for a time, be rendered harmless thereby.”

A preliminary report on the artesian basins of Wyoming, W. C. KNIGHT (*Wyoming Sta. Bul. 45*, pp. 107–251, pls. 26, map 1).—This is a preliminary treatise on the geology and artesian basins of Wyoming, based upon field notes collected during the past four years, accompanied by a map embodying “all that is known of the geology of Wyoming up to date,” the object of the publication being to explain the essential features of the artesian basins of the State, so that artesian wells may

be located. It is stated that nearly all available water of the streams of the State has already been appropriated, so that an increased supply for the future can be secured only from underground sources. "Artesian basins are numerous in Wyoming, and some of them are very large and especially well located." Twelve such basins are described in this bulletin, namely, the Big Horn, the Shoshone, Powder River, Green River, Sweetwater Valley, Laramie, the Shirley, Cheyenne, the Carbon, the Uinta, the Gros Ventre, and the Teton. No systematic attempts to develop the water resources of these basins have been made, but, "judging from the source of the water in many of the Wyoming basins, the artesian wells in this State should equal any that have been drilled in South Dakota."

Lysimeter experiments in 1899, J. HANAMANN (*Ztschr. Landw. Versuchsw. Oesterr.*, 4 (1901), pp. 34-39; *abs. in Chem. Centbl.*, 1901, I. No. 5, p. 270).—The drainage water obtained during 1899 contained a smaller percentage of salts than that of the previous year (E. S. R., 10, p. 930), due to the fact that a compact alluvial soil was used and percolation was slower. The greatest loss of nitrogen in the drainage occurred in case of bare soil, the order of losses in other cases being (1) soil bearing young red clover, (2) that under flax and beans, and (3) that under summer grain. Lime was the constituent most easily removed from the soil. The losses of potash and soda were practically the same. Chlorin and sulphuric acid were removed in considerable quantities, especially in bare soil. Phosphoric acid could scarcely be detected in the drainage water of soils bearing crops. In bare soils traces were found.

The lime compounds of cultivated soils and the determination of assimilable lime in soils, D. MEYER (*Landw. Jahrb.*, 29 (1900), No. 6, pp. 913-1000; *Fühling's Landw. Ztg.*, 49 (1900), Nos. 22, pp. 842-847; 23, pp. 865-871; 24, pp. 904-910; *abs. in Deut. Landw. Presse*, 28 (1901), No. 7, pp. 46-48, figs. 3).—Chemical and physical analyses and pot tests of 26 samples of two classes of soils—light and heavy—are reported in detail. The lime content of the soils examined varied from 0.092 to 1.271 per cent. The average for light soils was 0.333 per cent; for heavy soils, 0.694. The average percentage of carbon dioxid was 0.052 per cent in light soils and 0.098 in heavy soils, the average for 22 of the samples being 0.045. In case of the light soils 25.7 per cent of the lime was in the form of carbonate; in case of heavy soils, 19.1 per cent. While a high percentage of carbon dioxid usually indicated a high percentage of lime in the soil, a small percentage of carbon dioxid did not always indicate a low lime content. Calcium humate was found in appreciable amounts only in a few cases. The solubility of the lime in 2 per cent hydrochloric acid varied in case of the light soils from 38.5 to 92 per cent, averaging 68.9 per cent; in case of heavy soils, from 66.6 to 90.2 per cent, averaging 78.4 per

cent. Of the total amount of lime present in the soils 24.1 per cent was found in particles from 0.2 to 6 mm. in diameter, 21.6 per cent in the fine sand, and 54.3 per cent in the dust (silt). In certain of the soils, especially the heavy soils, a considerable proportion of the lime was apparently in the form of silicate. As regards the influence of the lime on the growth of plants as determined in pot experiments, the various lime compounds tested stood in the following order, beginning with the highest: (1) Carbonate and caustic lime, dolomite, and basalt; (2) Thomas slag, scolecite, anorthite, diabase, and nephelinite; (3) apophyllite; (4) phosphorite; (5) dicalcium phosphate and apatite; (6) fluorspar, and (7) monocalcium phosphate. Gypsum gave negative results. The highest yields were obtained when a mixture of calcium carbonate, magnesium carbonate, burnt lime, and burnt magnesia was applied. Of the phosphates, Thomas slag gave the best results, dicalcium and monocalcium phosphate the poorest. The poor results obtained with the superphosphate are attributed to the fact that it failed to neutralize the acid condition of the soil. Of the silicates, the zeolites gave specially good results. The results with gypsum are in direct contradiction to those usually obtained in practice. Even in case of leguminous plants the gypsum was without beneficial effect. The amounts of lime dissolved by concentrated and dilute hydrochloric acid bore no relation to the yield of crop or to the amount of lime assimilated. Neither did the carbon dioxid content furnish a reliable index of the amount of lime taken up by the plant, since a low percentage of carbon dioxid did not always indicate a deficiency of available lime. There was no appreciable difference in the lime content of the grain of rye grown on limed and on unlimed soils. The percentage of lime in the straw was increased by liming only when there was no increased yield. The active forms of lime in the soil are undoubtedly carbonate, sulphate, and easily decomposable silicates. The proportions of these which are most available for plant growth may be determined by treatment with neutral solutions of ammonium chlorid or ammonium nitrate. Digestion for 3 hours with 10 per cent ammonium chlorid solution at 100° C. on a water bath is considered a satisfactory means of accomplishing this. This method has decided advantages over the old method of digestion in 10 per cent hydrochloric acid, since the lime can be directly determined without separation of silica. Moreover, the results obtained show a closer agreement with crop results and with the amount of lime taken up by plants. A lime content of 0.25 per cent by this method is considered normal. Less than 0.2 per cent indicates a deficiency of lime in the soil.

The distribution of alkali in the soil of the experiment farm,
E. E. SLOSSON (*Wyoming Sta. Rpt. 1900, pp. 4*).—Determinations of the amount of alkali in the soil at depths of from 3 in. to 3 ft. on

different parts of the experiment farm are reported. The method followed in making these determinations was as follows:

"One hundred grams of soil was put into a glass-stoppered bottle with 200 cc. of distilled water and left for several days with occasional shaking. When it is settled a convenient quantity is drawn off with a pipette and without filtering evaporated to dryness and heated at a temperature above 250° C. for 2 or 3 hours. By this heating the gypsum becomes dehydrated and almost insoluble, so all that is necessary is to extract with a small amount of water, filter and evaporate in a platinum dish for total alkali and titrate for chlorids. For dehydration a small round air bath was made of Russia iron covered with asbestos and containing a rack for holding six smaller porcelain evaporating dishes. A number of experiments made with this method showed that it reduced the amount of soluble salts by about 60 per cent, while chlorids remained the same and different amounts of water could be used without affecting the results."

Soils of Mississippi. W. L. HUTCHINSON, W. R. PERKINS, and E. B. FERRIS (*Mississippi Sta. Bul.* 65, pp. 19).—Chemical and mechanical analyses are given of 375 samples of representative soils from different parts of the State, together with a map showing the location and extent of the different soil areas and a discussion of the analytical results. A comparison of the analytical results with the observed productiveness of the soils shows that "other things being equal, soils containing the largest total amounts of plant food will have the most plant food available for crops . . . and the deepest surface soils give the best yields." However, other conditions, especially a uniform water supply, are also essential to productiveness. In the soils examined 0.07 to 0.1 per cent of phosphoric acid was apparently sufficient for maximum yields. Soils containing 0.05 per cent of phosphoric acid or less, required applications of phosphoric acid. All of the soils examined, except those consisting largely of organic matter, contained a sufficient supply of lime. "There is no evidence that the application of potash as a food for plants has helped or increased the yield of any crop on any soil in this State." The use of leguminous crops to increase the nitrogen supply of the soil and improve the water conditions is especially recommended. Attention is called to the unproductiveness of recently exposed subsoils.

A study of the agricultural value of the soils of Madagascar, A. MÜNTZ and E. ROUSSEAU (*Bul. Min. Agr. [France],* 19 (1900), No. 5, pp. 910-1123, map 1; *Ann. Sci. Agron.*, 1901, I, No. 1, pp. 1-98, 152-160, map 1; *Compt. Rend. Acad. Sci. Paris*, 132 (1901), No. 8, pp. 451-456).—Chemical analyses of about 500 samples of soils collected in different parts of Madagascar, but especially in the mountainous region on the east coast, are reported, with mechanical analyses of certain of the typical soils. The samples and the regions from which they were obtained are briefly described and the results of the examinations are discussed in their relation to the agricultural possibilities of the island. The larger part of the area of the island is occupied by very ferruginous red soils. They are deficient in lime

and potash and especially poor in phosphoric acid. They are in addition very compact and impermeable and difficult to cultivate. They are easily washed by rains and harden and crack in time of drought.

The composition of some Herzegovinian and Macedonian soils, W. BUSCH (*Ztschr. Landw. Versuchs. Oesterr.*, 3 (1900), pp. 637-694; *abs. in Chem. Centbl.*, 1900, II, No. 25, p. 1248).—Mechanical and chemical analyses are reported of tobacco soils from these regions undertaken with a view to determining whether the quality of the tobacco was dependent upon the character of the soil or of the fertilizers used. The Herzegovinian soils were calcareous, but, with one exception, poor in calcium carbonate. The Macedonian soils were loamy, but uniformly rich in calcium carbonate. The results indicate that the brittleness of the Herzegovinian tobacco after drying as compared with the Macedonian tobacco can not be attributed to the abundance of lime in the soil. General suggestions regarding the fertilizing of the soils are made.

The geological agronomic charting of soils as a basis for their general valuation, J. HAZARD (*Landw. Jahrb.*, 29 (1900), No. 6, pp. 805-911, charts 11).—The soils of certain areas in North Saxony are charted on the basis of their observed adaptability to the more important crops and of their geological, petrographic, and physical examination. The methods employed are described and the results obtained are reported and discussed in detail. A close correlation was observed between physical properties and adaptability to crops. The methods followed are claimed to furnish a reliable basis for the valuation of soils and for the selection of crops best suited to them.

Subterranean waters, C. MORRIS (*Jour. Franklin Inst.*, 151 (1901), No. 3, pp. 182-194, figs. 2).—The origin, distribution, and geological functions of subterranean waters are discussed.

Contribution to the study of subterranean waters, F. MARBOUTIN (*Compt. Rend. Acad. Sci. Paris*, 132 (1901), No. 6, pp. 365-368).—A brief account is given of a study by means of fluorescein of the source and rate of circulation in the soil of subterranean waters from which the water supply of Paris is derived.

The soils of Allegany County, C. W. DORSEY (*Maryland Geological Survey, Allegany County*. Baltimore: Johns Hopkins Press, 1900, pp. 195-216).—This article discusses the forces which are active in the formation and the factors determining the productive capacity of soils; briefly reviews previous work on the soils of the county, including that of Whitney (*E. S. R.*, 4, p. 17; 5, p. 162), and describes 17 type soils found in the county. Mechanical analyses of these type soils and subsoils are also given.

"The soils of Allegany County are so closely related to the geological formations from which they are derived that a knowledge of the rock formations throws much light upon the soils which are found there." The type soils described are therefore given the names of the geological formations from which they are derived.

Analyses of rocks in the laboratory of the U. S. Geological Survey, 1880-1899, F. W. CLARKE (*Bul. U. S. Geol. Survey*, No. 168, pp. 308; XIII).—This is a revised edition of the second part of Bulletin 148 of the Survey, and includes, in

addition to analyses of various rocks and minerals, detailed mineral analyses of clays, soils, etc.

On the examination of soils with reference to assimilable plant food, O. KELLNER (*Fühling's Landw. Ztg.*, 50 (1901), No. 2, pp. 71, 72).—Referring to Meyer's recommendation (see p. 1020) that ammonium chlorid solution be used for the determination of the assimilable lime in soils, the author calls attention to his earlier experiments with the same method which were reported in 1887.¹

The determination of assimilable lime in soils, D. MEYER (*Fühling's Landw. Ztg.*, 50 (1901), No. 3, pp. 128, 129).—A reply to Kellner's claim of priority regarding the method used by the author (see above).

Need for humus in soils of western Kansas, R. W. CLOTHIER (*Industrialist*, 27 (1901), No. 19, pp. 241-243).—A brief explanation of the causes of the decrease of humus in these soils and the urgent need of restoring it.

What rôle does humus acid play in nature? H. BORSTRÄGER (*Oesterr. Chem. Ztg.*, 3 (1900), No. 21, p. 516).—The action of humus acid in absorbing moisture and fertilizing constituents and giving them out again as required by the growth of plants is briefly explained.

The cultivation of the soil in warm regions, G. PATUREL (*Ann. Agron.*, 27 (1901), No. 1, pp. 45-62, fig. 1).—This article describes the climatic conditions in Tunis and reports results of experiments on the influence of cultivation on the conservation of moisture in the soil of the southern or arid portion of this country. The results of these experiments show that by deep and thorough cultivation the rainfall of the period from November to April may be stored and conserved to such an extent that the growth of crops during the dry months, May to October, may be decidedly promoted and the amount of irrigation required materially reduced.

New problems in soil inoculation, J. S. STOKLASA, F. DUCHÁČEC, and J. PITRA (*Ztschr. Landw. Versuchs. Oesterr.*, 4 (1901), pp. 10-29; *abs. in Chem. Centbl.*, 1901, I, No. 5, p. 269).—See E. S. R., 12, p. 325.

FERTILIZERS.

Phosphorite and green manuring, A. N. ENGELHARDT (*Ztschr. Landw. Versuchs. Oesterr.*, 3 (1900), pp. 631-648; *abs. in Chem. Centbl.*, 1901, I, No. 4, p. 232).—From 3 years' field experiments the author concludes that the soils which responded to applications of fine-ground phosphorite were those in which the phosphoric acid was in form of apparently unassimilable organic compounds not set free by calcium carbonate (chalk). The fine-ground untreated phosphate was especially effective on cereals, the effect depending upon the percentage of calcium phosphate in amorphous form. The finer the meal the more effective the phosphate. The best results were obtained with rye, but the following crop of oats was also benefited. When the phosphorite was applied to rye, oats, or flax, and these crops were followed by a crop of rye to which barnyard manure was applied, the yield of the latter was much greater than that of rye which had received only an application of barnyard manure. The ground phosphorite can be profitably used to supply a deficiency of assimilable phosphoric acid on all soils which contain a sufficient amount of nitrogen, potash,

¹ Landw. Vers. Stat., 33 (1887), p. 359.

and lime. On soils which give a good yield without barnyard manure it does not prove profitable. An application of chalk improved the action of the phosphorite. How long the application of ground phosphorite may be continued with profit is a matter of doubt. When its action ceases, green manuring should be resorted to. Other mineral substances, especially marl, should be used in connection with the phosphorite.

On the utilization of fluorin gas obtained in the manufacture of superphosphates, C. ELSCHNER (*Chem. Ztg.*, 24 (1900), No. 75, p. 795, fig. 1).—The gaseous fluorin products formed during the treatment of mineral phosphates with sulphuric acid are conducted through a tower into which a water spray is introduced, which absorbs the gases. The fluorin compounds thus obtained are utilized as a preservative for manure in the following way: (1) Fullers' earth and similar materials are mixed with as much sulphuric acid as they will absorb without destroying the powdery nature of the materials, and (2) a solution of the fluorin compounds obtained as above is treated with enough dried and ground clay to convert the fluosilicic acid into stable salts. Equal parts of the two preparations when mixed and sprinkled over the moist manure generate fluosilicic acid.

The guano deposits of Eritrea, G. AMPOLA (*Staz. Sper. Agr. Ital.*, 34 (1901), No. 1, pp. 53-59).—Analyses and tests on different crops are reported.

An experiment on soil improvement, C. S. PHELPS (*Connecticut Storrs Sta. Rpt.* 1899, pp. 205-208).—This is a brief account of experiments begun in 1899 to test the relative value of (1) stable manure, (2) a complete chemical fertilizer, and (3) green manures, both alone and in combination with mineral fertilizers, as means of improving worn-out soils. The experiments are being conducted on eighth-acre plats. The same crop will be grown on the whole field in the same year and the crops will vary from year to year in the following order of rotation: Corn, potatoes, oats and peas for fodder, and soy beans. The yields of corn and stover from the different plats in 1899 are given without comment.

The distribution of fertilizers and their effects, BERTHAULT (*Ann. Agron.*, 26 (1900), No. 9, pp. 417-430).—Experiments at Grignon and elsewhere bearing upon the effectiveness of fertilizers applied in rows, hills, and broadcast are reviewed. These, it is claimed, show that fertilizers are most effective when localized in the soil (as in hills and drills) and not distributed throughout its mass (as in broadcast application). By localization the fertilizing constituents are protected from absorption by the soil and kept available for the plant. Practical methods of securing this localization under different conditions are explained.

The phosphate industry in the United States, K. PIETRUSKY (*Oesterr. Chem. Ztg.*, 4 (1901), No. 2, pp. 33-36).—A brief account of this industry, compiled from data reported in *The Mineral Industry*, volumes 1 to 8.

The preparation of marketable superphosphates, C. ELSCHNER (*Chem. Ztg.*, 25 (1901), Nos. 7, pp. 68, 69; 8, pp. 81, 82).—Brief descriptions are given of various patented and unpatented processes of preparing concentrated and easily handled superphosphates.

Is the arsenic in superphosphates harmful? A. STUTZER (*Deut. Landw. Presse*, 28 (1901), No. 9, p. 61).—The percentage of arsenic in superphosphate (usually 0.011

to 0.02 per cent, sometimes as high as 0.05 per cent) is considered entirely too low to render plants grown on soils fertilized with superphosphates poisonous, as has been suggested in regard to barley used for beer making.

Potash in agriculture, G. SMETS (*La potasse en agriculture. Maaseyck: Vanderdonck-Robyns, 1900, 2. ed., pp. 44, pls. 7*).—This is the second edition of this brief treatise on the use of potash as a fertilizer, which is based mainly upon the results of experiments made by the author in Belgium.

Analyses of commercial fertilizers, M. A. SCOVELL, A. M. PETER, and H. E. CURTIS (*Kentucky Sta. Bul. 88, pp. 125-173*).—This bulletin contains a statement of the number of brands of fertilizers collected and examined, the general results of the analyses, explanations regarding free analyses, the terms used in reporting analyses, and the valuation of fertilizers, and tabulated analyses and valuations of 361 samples. Of the samples analyzed, "72, representing 55 brands and 22 firms, fell so far below the guaranteed analyses in phosphoric acid, nitrogen, or potash, or in two or all three of these ingredients as to be unaccounted for by variations in sampling or analysis."

Report of analyses of commercial fertilizers for the spring and fall of 1900, L. L. VAN SLYKE and W. H. ANDREWS (*New York State Sta. Bul. 177, pp. 37-97*).—The results of analyses of 450 different brands of fertilizers are reported. Of these 326 were complete fertilizers in which the nitrogen varied from 0.44 to 8.15 per cent, averaging 2.16 per cent. The amount of water-soluble nitrogen varied from 0 to 7.1 per cent, averaging 0.89 per cent. The available phosphoric acid varied from 1.2 to 17.47 per cent, averaging 8.9 per cent. The potash varied from 0.27 to 12 per cent, averaging 4.84 per cent. In 64 out of the 326 brands examined, the potash was in the form of sulphate free from an excess of chlorides. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed averages by 0.1, 1.28, and 0.41 per cent, respectively. The average retail selling price of the fertilizers was \$27.20, the retail cost of the separate ingredients unmixed, \$19.72.

FIELD CROPS.

Various conditions affecting the malting quality of barley, J. M. H. MUNRO and E. S. BEAVEN (*Jour. Roy. Agr. Soc. England, 3. ser., 11 (1900), pt. 2, pp. 185-251, pls. 11*).—A comprehensive paper treating of the following phases of the subject: Varieties; cross fertilization; coincident relations of size of grain, maturation, and percentage of nitrogenous matter; physiological aspect of maturation and overmaturation; conditions affecting quality, as climate, soil, culture, and change of seed; and the effects of cultural treatment of barley grown after roots, deducible from the Rothamsted rotation plats. Under the latter caption the results obtained at Rothamsted with barley grown continuously on the same ground 48 years, and also in a 4-year rotation of roots, barley, clover (or beans) and wheat for 52 years or 13 complete rotations, are considered. On some plats the roots in the rotation were fed on the land while on others they were removed. Fallow was regularly substituted for clover (or beans) on some plats.

Malting barleys most generally grown in the United Kingdom are the narrow-eared two-rowed variety (*Hordeum distichum*), of which Chevalier is the main type grown, and the wide-eared variety Gold-

thorpe. The Goldthorpe types show greater tendency to deterioration than the Chevalier. On the other hand they possess a stouter straw and have the ability to stand up under weather conditions that would lodge Chevalier. A number of other subspecies and varieties of barley are considered and some data and illustrations given of early types of barley. The wide-eared type of barley is thought to be the older.

Relative to the improvement of varieties of barley the author states that—

“the heavier the straw, the coarser and therefore the lower in value will be the grain generally. A low ratio of grain to straw usually goes along with grain with high content of nitrogenous matters and defective maturation. A large coarse grain of high weight per bushel is not as good malting material as a smaller grain well matured. In fact (given vitality) maturation is the most important quality of barley from a malting point of view and generally with the varieties at present cultivated the smaller grain is the better matured. If by means of selection or cross fertilization varieties of larger body but maturing equally well can be secured, a great step in advance will be made.”

The subject of maturation is considered at considerable length:

“Maturation is physiologically a post-ripening process, the character of which depends largely on the pre-ripening and this in turn on the soil conditions. Too early ripening on thin soils, due to drought and too late ripening on strong soils, both give a highly nitrogenous grain which will not mature well even under favorable natural conditions and is always more or less steely and unworkable. Even with well-ripened grain, maturation depends on sufficient time being allowed before and after cutting, but above all on weather conditions.”

In the Rothamsted experiments with barley the roots on certain plats were unmanured. Other plats received superphosphate only, while others received mixed minerals and nitrogenous material. The effect of these fertilizers on the barley crop are summarized as follows:

“The good effect of soluble phosphates on quality of grain is most marked. The plats manured with minerals only have given the best yield of grain in proportion to straw, showing the unmistakable effect of phosphates in assisting grain formation. This series of plats also shows a lower percentage in the grain of nitrogenous matters than either of the other series. The barley, though often comparatively small, is well matured—better in this all-important respect than where no phosphates are applied, and also better than where, with heavy nitrogenous dressings in addition to minerals for the preceding roots, the land is in better condition and gives much higher yields.”

There was not much difference as regards quality of barley whether the roots in the rotation plats at Rothamsted were fed or removed, though the yields were much heavier on the “fed” plats. The maturation of the grain was frequently, but not always, better where the roots were removed. This difference was counterbalanced in a measure by the higher relative market value of the grain from the “fed” plats. The general opinion that the feeding of roots on the land with oil cake added to the ration is too good a preparation for barley, especially as regards the quality of the barley grown on such land, was not controverted in these experiments. The authors believe that all the

various cultural conditions combined have less influence on quantity and quality of produce than has the weather; and the fact that barley does not want for quality too high a condition of soil points to the wheat crop as the best preparation for barley.

Some tests relating to the culture of barley, A. PAGNOUL (*Ann. Agron.*, 26 (1900), No. 11, pp. 561-567).—Some pot experiments were made to determine the influence on barley of (1) growing in sandy, clayey, and limy soils, respectively; (2) of excessive dryness or humidity, and (3) of an excess of phosphoric acid or nitrogen. Rust seriously attacked the plants, but the results obtained are thought to be comparative. Pots of each of the different soils were placed in two groups. One group received about the same amount of water as would fall naturally in a dry year; the other, double this amount, or corresponding to a naturally wet year. Three pots in each group received nitrogen and 3 phosphoric acid in excess. The yields obtained in the well-watered pots were more than double for straw and nearly double for grain those obtained in the scantily watered pots. Nitrogen increased the yield of straw, but the yield of grain was less than where phosphoric acid had been used. It also increased the nitrogen content and diminished the starch content of the grain. The phosphate, on the contrary, yielded harder, drier grain, containing less nitrogen and richer in starch and phosphoric acid.

Field experiments with fertilizers, W. O. ATWATER and C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1899*, pp. 168-204, *dqms.* 3).—This report includes the results for the last three years of experiments on corn, cowpeas, and soy beans, to determine the effects of nitrogen in different quantities and combinations in the fertilizers applied and, further, the results of a rotation soil test. The results for each of the three years are given in tabular form and discussed at some length. The experiments have now been carried on for a number of years. The results of the soil test for a period of ten years are summarized. Previous reports have been given in former publications (*E. S. R.*, 9, p. 746). The fertilizer applications consisted of quantities of bone-black, furnishing 53 lbs. of phosphoric acid per acre; muriate of potash, furnishing 82 lbs. of potash per acre; and different quantities of nitrate of soda and sulphate of ammonia, giving 25, 50, and 75 lbs. of nitrogen per acre.

The experiments with corn showed that a fertilizer application of nitrogenous and mineral fertilizers is much more effective than mineral fertilizers alone. Quantities of nitrogenous fertilizers supplying from 25 to 50 lbs. of nitrogen per acre, in connection with liberal quantities of phosphoric acid and potash, are recommended. In most cases, the largest percentages of protein in the crop were found where the largest quantities of nitrogen were used in the fertilizers. The yield of the leguminous crops was but slightly increased by the use of

nitrogenous fertilizers as compared with the use of mineral fertilizers. The average results in the experiments with cowpea fodder showed no advantage in the use of nitrogenous fertilizers.

In the test with soy beans grown for seed the increase due to nitrogen in the fertilizers was small. The authors infer that where mineral fertilizers are abundantly available, nitrogen has very little beneficial effect on either the total yield or the feeding value of cowpeas and soy beans.

The results of the soil-test experiments indicated that the fertilizer requirements depended more upon the crop grown than upon the soil. Corn and oats seem to require phosphoric acid and nitrogen, and potatoes potash. The indications in connection with soil tests, conducted throughout the State for a number of years, are that in many cases it is the soil rather than the crop which regulates the fertilizer requirements. From these results it is inferred that it is necessary to study and test a soil to learn its deficiencies and needs.

Fertilizer experiments during 1900, C. A. MOOERS (*Tennessee Sta. Bul., Vol. XIII, No. 3, pp. 23, figs. 3*). The experiments reported in this bulletin consist of tests with fertilizers on potatoes, corn, cowpeas, and peanuts, and the effects of fertilizer applications on the germination of the seeds of these crops. The results are given in tabular form and discussed.

The experiments with potatoes showed the best results from the use of a complete fertilizer containing high percentages of nitrogen, phosphoric acid, and potash. Cotton-seed meal proved a more profitable source of nitrogen than nitrate of soda, and a mixture of the two was unprofitable. Potatoes fertilized with a complete fertilizer averaged 2.74 per cent higher in starch than potatoes grown without fertilizer, and 1 per cent higher than those fertilized with nitrogen and phosphoric acid only. Potatoes grown on the Cumberland Plateau averaged 0.79 per cent higher in starch than those grown in the Tennessee Valley. The use of fertilizers in growing corn on rich soil was not profitable, but on soil of even more than average productiveness, which had produced corn and small grains consecutively for many years, the yield was profitably increased by heavy applications of acid phosphate and nitrate of soda. It was shown that phosphoric acid was the most necessary element. Nitrogen in the fertilizer increased the protein content of the grain. With cowpeas, phosphoric acid produced a larger yield of pods and peas than when applied in conjunction with potash, but the use of the two elements produced a larger yield of cowpea hay. Nitrogen was not found advantageous, and potash used alone was unprofitable. In the experiments with peanuts, nitrogen applied with phosphoric acid and potash lowered the grade of the nut by producing a thicker hull.

In several instances accidental failures took place, and in the second course of the rotation the experiments on some of the plats were discontinued. The two plats carried completely through the two courses of rotation showed net losses of \$18.40 and \$44 per acre in the first course, but in the second course they showed gains of \$80.70 and \$64.40 per acre, respectively.

Researches on the growth of forage plants, MONVOISIN (*Ann. Agron.*, 26 (1900), No. 2, pp. 77-103).—A study was made of the water, ash, and nitrogen content of vetch, crimson clover, lentils, sainfoin, alfalfa, blue melilot, Italian and English rye grass, and a number of less known forage plants at different stages of growth. The weights of the stem and roots, etc., were also determined.

The roots of perennial plants were found to represent a rather high weight in proportion to the stems. After the seeds mature a constant loss of dry matter was found to occur. The mineral matter was greater in the roots than in the stems and more abundant in perennials than in annuals. It was highest at a period intermediate between the beginning of vegetation and flowering, and diminished toward the end of vegetation. In these investigations the nitrogenous material of the different plants was greater April 26 than at any period thereafter.

Grains, forage crops, and plants for green manuring, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1900*, pp. 155-158).—The experiments with grains included tests of wheat grown for milling purposes, and the determination of the best varieties of cereals for hay. Of fifteen varieties of wheat tested, Rugby yielded as high as Sonora, the standard variety of the region, and No. 1174 of the U. S. Department of Agriculture from Turkestan ripened in as short a time. The results further indicated that Sonora wheat yields best when sown soon after November 1. Wheat sown broadcast and irrigated by furrows gave the best returns, as compared with other methods of irrigating. Feldspar wheat produced a better hay than Sonora, and the hulless and beardless varieties of barley were considered preferable to bearded varieties for hay.

Club-head sorghum was the best yielding forage crop. Kafir corn was next to sorghum in yield. Teosinte gave a good yield of good fodder but required too much water to be desirable for that region. Egyptian corn was the best heat and drought resisting of the forage crops tested. Yellow sweet clover (*Melilotus indica*) proved a better plant for green manuring, under the conditions, than alfalfa and lupines.

Grass experiments, W. CARRUTHERS and J. A. VOELCKER (*Jour. Roy. Agr. Soc. England*, 3. ser., 11 (1900), pt. 1, pp. 116-138).—The results are given of 22 trials in 11 counties of England in the improvement of pastures by fertilizing. In 10 cases where analyses showed a lack of phosphoric acid, the addition of fertilizers containing that

chemical was found profitable in practice. The same fact was borne out in the case of lime, chemical analyses indicating where it could be profitably used. Basic slag was found to be a valuable fertilizer for pastures, and its influence continued through several seasons. Superphosphate proved to be valuable, but the influence was not as lasting as in the case of slag. Stable manure produced one heavy crop which was, as a rule, rejected by stock on account of the presence of the manure. The returns from its use rapidly diminished in the following season.

Memoir on the commercial culture of potatoes, M. P. LAVALLÉE (*Bul. Soc. Agr. France, n. ser., 31* (1900), *Apr. 15, pp. 461-493; May 1, pp. 555-557*).— Besides discussing the advantages of potato culture the author presents the results of experiments with potatoes along the following lines: Tests of sprouted *v.* unsprouted potatoes for seed as regards both yield and starch content of the potatoes harvested, distance experiments, planting different sized tubers for seed, experiments to determine the effect on the starch content of the crop of planting tubers containing different percentages of starch, experiments in changing the physical characters of potatoes as regards the color of skin and color and quality of the flesh, selection of different parts of the tuber for seed, and spraying to control blight, etc. Notes on potato culture and on the cost of growing potatoes are also included. The experiments extended over a period of years, and in some instances are given in considerable detail.

The results obtained in the experiments show the advantages of using sprouted potatoes for seed to be an increased total yield, increased earliness, larger starch content, and a more vigorous growth of vines. Planting tubers in rows 2 ft. apart and 1 ft. distant in the row gave better results than greater distances. It increased the yield and hastened the maturity of the crop. The tubers were better formed and richer in starch. Average sized whole tubers used for seed gave better returns than large or small sized whole tubers. Small seed, while possessing great vigor of reproduction, tends to the production of small tubers. Large tubers may be profitably cut for seed. Pieces weighing on an average 45 gm. and carrying 2 eyes were better for seed than whole tubers of the same weight. The advisability of cutting seed tubers largely hinges on the variety to be planted. With Peach Blow, Magnum, Bruce, and Maereker, the best results were obtained when the tubers were cut; while with Blue Giant, Red Skin, Hebe, and Pluto, results were generally better with the whole tubers. No decided results were obtained in planting tubers of different starch content. In connection with this work the author noticed that tubers having the highest percentages of starch were usually of a dark color and not smooth. Bordeaux mixture prolonged the growing period of potatoes and increased the yield.

Experiments with sugar cane, W. MAXWELL (*Hawaiian [Sugar Planters'] Sta. Rpt. 1900, pp. 3-40, 43-50*). The work here reported comprises planting tests and an investigation of the chemical composition of different varieties with a view to determining the quantities of plant food removed from the soil and how they should be returned to it. The results of the planting tests are illustrated in the following table:

Different methods of planting Lahaina and Rose Bamboo sugar cane, with average results obtained.

Methods of planting.	Canes per row.	Yield per acre.	Density of juice.	Sugar in juice.	Purity coefficient.	Sugar in cane.	Sugar per acre.
		Lbs.		Per ct.		Per ct.	Lbs.
Two continuous canes in row . . .	382	185,660	20.72	17.57	84.79	15.74	29,212
One continuous cane in row . . .	313	193,180	19.94	17.09	85.71	15.31	29,575
One eye per 6 in.	387	194,660	19.99	16.95	84.79	15.18	29,549
One eye per 12 in.	387	195,940	19.97	17.32	86.73	15.51	30,390
One eye per 18 in.	359	175,036	20.00	16.95	84.75	15.18	26,570

Other experiments along this line are in progress.

Comparative tests of 13 varieties of cane, comprising 4 varieties already upon the islands and 9 introduced canes, were conducted under identical conditions. The canes used for seed were 15 months old. The relative results are given in the following table.

Results from different varieties of cane.

Varieties.	Canes per row.	Yield per acre.	Fiber in the cane.	Sugar in cane.	Sugar in juice.	Purity coefficient.	Density.	Sugar per acre.
		Lbs.	Per ct.	Per ct.	Per ct.			Lbs.
Lahaina	319	193,280	10.9	15.32	17.20	86.25	19.93	29,610
Rose Bamboo	340	209,600	9.9	14.54	16.15	85.35	18.72	30,475
Yellow Caledonia	254	182,240	11.7	12.36	14.00	78.15	17.87	22,524
Yellow Bamboo	297	158,160	12.8	13.12	15.05	81.58	18.45	20,750
Moore Purple (Fiji)	490	80,560	10.3	12.60	14.05	79.15	17.75	10,150
Demarara, No. 117	412	186,240	10.1	12.45	13.85	75.58	18.35	23,186

The results of analyses of the mineral matter in the leaves, tops, and dead cane of the different varieties are given in tables. From July, 1898, to November, 1899, inclusive, the crop received 26.99 in. of rain and 76 in. of irrigation water. This increased the yield of sugar per acre by 23,155 lbs. as compared with results on unirrigated plats. Fertilizer tests in progress are briefly described.

Wheat experiments, C. L. NEWMAN (*Arkansas Sta. Bul. 62, pp. 17-34, fig. 1*).—These experiments embraced culture, rotation, seeding, and variety tests with wheat. Plowing deeper than 8 in. did not prove profitable. Disking and rolling the soil thoroughly before sowing and thorough preparation of the soil in general diminished winterkilling and the bad effects of drought and increased the yield materially. Sowing 5 and 6 pecks of seed per acre gave the best returns. Where cowpeas, soy beans, and beggar weed were grown on light sandy soil the yield of the following wheat crop was increased 56.5 per cent. The returns indicate that crops for green manuring should not be plowed under shortly before the crop is sown. This was shown by the fact that where stubble of leguminous plants and the whole plants were plowed under shortly before sowing, the results were generally in favor of the stubble. A crop of cowpeas grown after harvesting rye and potatoes increased the following wheat crop 30 per cent.

“Wheat grown continuously on the same ground for three years and each crop preceded by a crop of cowpeas gave an increased yield of 46.7 per cent as compared with breaking the wheat stubble and not sowing cowpeas. Fertilizing cowpeas with 200 lbs. of acid phosphate and 100 lbs. of muriate of potash increased the yield of wheat that followed 58 per cent. Wheat sown upon cowpea stubble, plowed under and fertilized with 400 lbs. of a complete fertilizer, gave an average increased yield of 64.4 and 78.5 per cent increased yield the second year over soil treated only in the usual way.”

Early Ripe, Indian Swamp, Purplestraw, Pool, Red May, Red Wonder, and Tennessee Fultz gave the best results.

Wheat (*Kentucky Sta. Bul.* 89, pp. 177-198, pls. 4).—This bulletin is a report on variety and fertilizer tests with wheat. Similar work has been previously reported (*E. S. R.*, 11, p. 731). Thirty-six varieties of wheat were grown in 1900. The yields of grain and straw per acre are tabulated for each variety. The botanical description of the varieties, with field notes on the same, and illustrations of 30 varieties, are given. Fultz wheat gave the largest yield, 52.2 bu. per acre; followed by Harvest King, 50.3 bu.; Lancaster Red, 49.9 bu.; White-seeded Golden Cross, 49.7 bu.; and Harvest Queen, 49.5 bu. Kansas Mortgage Lifter and Turkish Red produced the heaviest grain, the bushel weighing 65 lbs. The fertilizer experiments were conducted on a farm in the region of the Coal-Measures formation. The results indicated the need of phosphoric acid and humus in the soil.

Experiments with winter wheat, A. M. SOULE and P. O. VAN-ATTER (*Tennessee Sta. Bul.*, Vol. XIII, No. 2, pp. 24, pl. 1, figs. 5).—These experiments included fertilizer and variety tests, intertillage experiments, and trials of different rates of seeding, and seed selection. The work and its results are discussed at some length and the yields obtained are given in tabular form. The results on small plats were relatively correct as compared with field trials. Early and thorough preparation of wheat land is recommended. Fulcaster wheat, with a yield of 41.66 bu. per acre, was the most productive variety, followed by Early Genesee Giant, with 41.35 bu. Improved Fulcaster, Niger, Fultz, and Poole averaged over 40 bu. per acre. Velvet Chaff produced the heaviest grain, the measured bushel weighing 61½ lbs., and Fultz, Poole, Harvest King, and Deitz Amber all weighed 60 lbs. or over, although yielding more than 39 bu. per acre. The best milling wheats were Fulcaster, Niger, Mediterranean, Improved Fulcaster, and Deitz Amber, while White Golden Cross, Early Genesee Giant, and Fultz were considered the poorest. Egyptian produced the weakest straw and Early Genesee Giant the stiffest.

Among 22 fertilizer combinations tested in this connection, 10 tons of barnyard manure produced the best results, increasing the yield 11.72 bu. as compared with wheat grown without a fertilizer application. Five tons of barnyard manure per acre increased the yield 7.71 bu., at a cost of 26 cts. per bushel. A home-mixed fertilizer used at the rate of 50 lbs. of nitrate of soda, 100 lbs. of Tennessee acid phosphate, and 25 lbs. of muriate of potash increased the yield 8.07 bu., at a cost of 27 cts. per bushel.

In discussing the cowpea as a source of nitrogen in soil renovation, the authors state that "nitrogen is chiefly stored in the leaves of the cowpea plant and not in the nodules on the roots, as many suppose."

Other results obtained indicated the best time for seeding wheat to be from October 1 to 15. The intertillage experiments consisted in cultivating, with a Breed's weeder, wheat grown in rows wide apart or

close together. The results show a gain of 2.13 bu. per acre in favor of the rows wide apart. The yields from sowing wheat at the rates of 1, 1½, and 2 bu. per acre did not differ materially, but the use of 2 bu. per acre is regarded best.

A test of other winter cereals gave very satisfactory results, Common Gray winter oats yielding 39.31 bu., Excelsior winter rye 51.78 bu., and winter barley 56.66 bu. per acre. Experiments in seed selection are in progress.

Wheat culture at the agricultural school at La Réole in 1898, 1899, and 1900, P. HERBET (*Jour. Agr. Prat.*, 1900, II, No. 50, pp. 863, 864).—The manner of conducting the experiments is described and observations on diseases, lodging, maturity of different varieties, and the yields are noted. On a sandy loam soil plowed 35 cm. deep, with a green manuring of crimson clover and an application of 500 kg. of superphosphate and 100 kg. of ammonium sulphate per hectare, a yield of 11 hectoliters was obtained from 3 liters of La Réole wheat sown, or 366 liters for each liter of wheat. The wheat was sown in drill rows, 35 cm. apart. The author calls attention to the advantages of selecting the seed, working the soil to a good depth, and manuring rationally. It is stated that the results confirm previous conclusions; that under existing climate and soil conditions of the valley of the Garonne a rather thin stand of wheat gives the best results.

Results of various culture and fertilizer experiments, H. E. STOCKBRIDGE (*Florida Sta. Rpt. 1899 and 1900*, pp. 12-20).—In the report of the agriculturist, several brief accounts of experimental work are given. Mexican June corn, with cowpeas as an intercultural crop, was grown after oats which were harvested late in May. Good crops of oats, corn, and cowpeas were obtained. Cultural tests with cassava resulted in the best yield from planting 4 ft. apart, with hills 3 ft. apart. A test of the continued use of Egyptian and sea-island cotton seed, without resorting to fresh supplies from the original sources, showed a decrease in yield, year by year, as the seed became removed in time from the seed originally procured. Other experiments with corn, sweet potatoes, and velvet beans are briefly described.

Field experiments (*Queensland Dept. Agr. Rpt. 1899-1900*, pp. 4-11).—A report on the field experiments, comprising culture and variety tests with potatoes, oats, malting barley, wheat, maize, millet, and various other forage plants, is here given.

Report of the agriculturist of the State experiment station at Albano, Sweden, 1897 1899, S. RHODIN (*Kgl. Landthbr.-Akad. Handl. Tidskr.*, 39 (1900), No. 4, pp. 207-226).—The report deals with methods of preservation of stable manure, fertilizer experiments for the production of grass seed, further trials of Wiborgh phosphate, and experiments with standard varieties of oats at different Swedish agricultural schools.

Concerning experiments with fertilizers, BEHRENS (*Mitt. Deut. Landw. Gesell.*, 16 (1901), Nos. 4, pp. 14, 15; 5, pp. 17-19; 6, pp. 21, 22).—A paper treating of the methods of conducting fertilizer experiments and the value and meaning of the results.

Experiments with phosphatic manures on cereals, E. MARRE (*Semaine Agr.*, 21 (1901), No. 1026, pp. 13, 14).—A report on cooperative experiments with phosphatic manures on cereals. The results indicate that a high-grade superphosphate is most economical.

The lodging of grain, C. GUFFROY (*Jour. Agr. Prat.*, 1901, I, No. 2, pp. 48, 49, figs. 3).—This article is a brief report on the study of several cereal crops grown under different fertilizer conditions, with a view to determining the relation between the fertilizer application and the lodging of grain. The conclusions are that the resistance of the grain depends upon the cellular structure of the stem, a purely mechanical quality. Phosphoric acid was shown to increase the resistance and nitrogen to decrease it. The application of both these elements in the proper proportions is considered necessary for a good yield of unlodged grain.

Four years' cooperative culture tests with barley, A. SEMPOLOWSKI (*Deut. Landw. Presse*, 28 (1901), No. 3, pp. 21, 22).—A condensed report on the results obtained with 4 varieties of barley. Hanna barley gave the highest yields of straw and grain.

Sea of Azof barley (*Jour. Dept. Agr. West. Australia*, 2 (1900), No. 6, pp. 423, 424).—Field notes on this variety of barley regarded as quick growing and suitable for early green fodder.

The quality of barley grown after roots, A. D. HALL (*Jour. Ed. Agr. [London]*, 7 (1900), No. 3, pp. 292-299).—This article considers the injurious effect on the quality of barley when this crop is grown after swedes and turnips, and suggests a remedy in the method of fertilizing. The application of fertilizers in its relation to this subject was made a study at the Southeast Agricultural College at Wye, and the results showed that when barley is grown after roots that have been fed on the land a dressing of salt injures the quality of the barley, and an application of sulphate of potash, although increasing the starch content of the grain, does not give profitable results. A dressing of 3 cwt. of superphosphate per acre produced a slight increase in yield and a marked improvement in quality.

Broom corn, J. T. ROBERTSON (*Jour. Agr. and Ind., South Australia*, 4 (1900); No. 5, pp. 424, 425).—Brief popular directions for growing broom corn.

Broom corn, TRABUT (*Bul. Agr. Algérie et Tunisie*, 6 (1900), No. 24, pp. 665-671, figs. 2).—A discussion of broom-corn culture in Algeria.

Fertilizer experiments with red beets, E. O. ARENANDER (*Landtmannen*, 11 (1900), No. 18, pp. 280-286).

The castor bean (*Florida Agr.*, 28 (1901), No. 3, pp. 33, 34).—This article treats of the culture and uses of the castor bean.

Fertilizer experiments with carrots, E. O. ARENANDER (*Landtmannen*, 11 (1900), No. 33, pp. 527-530).

Japanese clover, F. GAGNAIRE (*Jour. Agr. Prat.*, 1901, I, No. 3, pp. 93-95).—An article discussing the first experiments with Japan clover in France and Algeria, the results of which were not promising.

Cowpeas and soy beans (*Jour. Dept. Agr. West. Australia*, 2 (1900), No. 6, pp. 436-438).—A popular article comparing the two plants.

Forage plants, B. C. BUFFUM and W. H. FAIRFIELD (*Wyoming Sta. Rpt.* 1900, pp. 34).—A report on investigations with a large number of cultivated and native forage plants, consisting of brief cultural notes on the different species and lists of promising and unpromising plants for the region, as shown by the results of trials.

Grasses and fodder plants on the Potomac flats, C. R. BALL (*U. S. Dept. Agr., Division of Agrostology Circ.* 28, pp. 18).—This report describes the trial grounds on which the grasses and forage plants were grown and notes the facts observed in connection with these tests. The seed for these trials was obtained in the United States and in foreign countries. A number of grasses from the Southwest, namely, curly mesquite, turnip grass, water grass, and sprangle made a very promising growth. The introduced Australian species showed a ready adaptability to this climate, and among them button grass and Mitchell grass made a remarkably vigorous growth. This report discusses about 60 different species, including perennial meadow and pasture grasses, millets, sorghums, teosinte, saltbushes, burnet, rape, and a large number of different leguminous crops.

Investigation on the composition of grasses from different meadows, A. EMMERLING ET AL. (*Centbl. Agr. Chem.*, 29 (1900), No. 12, pp. 804-807).—The results of analyses are tabulated. The authors conclude that the food value of a grass mixture can be determined only by analysis.

Fertilizing meadows on granitic soils, L. GRANDEAU (*Jour. Agr. Prat.*, 1901, I, No. 2, pp. 45, 46).—This article compares the use of superphosphate and Thomas slag in this connection, and concludes that under the conditions which are discussed Thomas slag is the more profitable.

Management of ensilage crops, A. M. SOULE (*Univ. Tennessee Record*, 4 (1901), No. 1, pp. 68-75, figs. 5).—A general discussion of the subject.

Revised notes on the cultivation of broom millet for manufacturing purposes, A. A. DUNNICLIFF (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1124-1129).—Popular notes on soil and seed requirements of broom corn, and on the planting, cultivating, harvesting, curing, and baling of the crop. A number of the most suitable varieties are described.

Observations on the culture of oats, RAYNAUD and BRUNERIE (*Semaine Agr.*, 21 (1900), Nos. 1027, pp. 22, 23; 1028, pp. 29, 30).—A résumé of cultural notes on oats during the years 1893-1899.

Potatoes, A. J. McCLATCHIE (*Arizona Sta. Rpt.* 1900, pp. 161, 162).—In a variety test with potatoes, Burpee Early matured first and gave a yield equal to that of Early Rose, a variety commonly grown. Early Rose planted February 7 yielded one-third more than when planted January 17. Triumph also gave promising results. Potatoes planted 9 in. apart in a row gave the best results as compared with other distances. Chile saltpeter applied at the rate of 500 lbs. per acre did not prove profitable.

The effect of shortening the root before planting root crops, KUNATH, (*Deut. Landw. Presse*, 27 (1900), No. 103, pp. 1237, 1238, figs. 3).—The opinions of different agricultural writers on the subject are given, and the results of experiments by the author along this line with celery are reported.

Conditions affecting the feeding value of mangolds and swedes, J. S. GORDON (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), pt. 2, pp. 25-33).—A description of experiments is given and the results obtained are tabulated. It was found that the best yielding variety does not contain the most nutriment, and that large roots are not so nutritious as small roots. Heavy manuring retarded the maturity of the crops.

Our saltbushes, T. E. GRIGG (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1120, 1121).—A popular discussion of the value of different varieties of saltbush.

Sugar beets, A. J. McCLATCHIE, R. H. FORBES, and W. W. SKINNER (*Arizona Sta. Rpt.* 1900, pp. 163-165, 184, 185).—The experiments here reported were conducted mainly for the purpose of testing methods of irrigation. Two plats of beets, sown December 26 and January 23, and first irrigated April 1 and April 3, respectively, produced beets high in sugar content and purity. The yield on the plat sown in December was 14.5 tons per acre and on the other, 10.4 tons. These results indicate that the best time to begin irrigating is when the beets are from 2 to 3 months old.

In addition to this work, sundry tests with beets were made on the Upper Gila, and the results are given. The season was adverse to the success of the experiments and the work is to be continued.

Experiments on the culture of sugar beets at Cappelle, (*Jour. Agr. Prat.*, 1901, I, No. 3, pp. 78, 79).—This is a report on a test of four different strains of sugar beets, designated as short, early, medium (*demi-longues*), and late. For three years in succession the medium sized and late maturing strains have given a larger yield in beets and in sugar than the short and early ripening strains. The results for 1900 are given in a table.

Planting small beets for seed production, E. SCHAAF (*Bl. Zuckerrübenbau*, 7 (1900), No. 24, pp. 369-376, fig. 1).—A discussion of the size of the beet to be used for this purpose.

Phosphoric acid as a fertilizer for sugar beets, G. SMETS (*Belg. Hort. et Agr.*, 12 (1900), No. 24, pp. 374, 375).—Note on the results of several experiments on the subject.

Applying nitrate of soda as a top-dressing in sugar-beet culture, L. GRANDEAU (*Jour. Agr. Prat.*, 1901, I, No. 1, pp. 17, 18).—This article is a discussion of experiments along this line, the results of which are not regarded as quite conclusive. The author suggests further investigation on the subject.

Sugar beet statistics for the year 1899-1900 (*Bul. Min. Agr. [France]*, 19 (1900), No. 5, pp. 900-902).—Tables showing the quantities of beets worked and the quantities of sugar and by-products obtained.

Report of the tobacco expert, R. S. NEVILL (*Queensland Dept. Agr. Rpt. 1899-1900*, pp. 37, 38).—A brief report on tobacco work in Queensland.

Experiments with wheat at the agricultural experiment station at Chevillcoy, J. R. CHAVEX (*Bol. Mens. Agr. y Gan.*, 2 (1900), No. 2, pp. 66-70).—A report on variety and culture tests with wheat.

Wheat in the Fassifern District (*Queensland Agr. Jour.*, 7 (1900), No. 6, p. 498, pls. 2).—A note on growing Allora spring wheat in that region.

Minnesota No. 163 wheat, W. M. HAYS and A. BOSS (*Minnesota Sta. Class Bul.* 8, pp. 4).—A popular bulletin giving a comparison of this wheat with other varieties, based on the results of tests made at the station. Comparative tests with this wheat were carried on throughout the State, and the results thus far obtained are discussed. In general this new fife wheat yielded more than the varieties with which it was compared.

Rietti wheat (*Agr. Jour. Cape Good Hope*, 17 (1900), No. 13, pp. 783, 784).—A tabulated report on cooperative experiments with this variety.

Variety tests of wheat, oats, and barley, B. C. BUFFUM and W. H. FAIRFIELD (*Wyoming Sta. Rpt. 1900*, pp. 44).—A brief description of the variety tests with wheat, oats, and barley is given, and the results of testing about 500 varieties of wheat, over 60 varieties of oats, and about 50 varieties of barley during the years 1896-1899, inclusive, are tabulated.

Work at the agricultural experiment station at Baradero, D. DEL CASTILLO (*Bol. Mens. Agr. y Gan.*, 2 (1900), No. 2, pp. 54-63).—A report on variety and culture tests with wheat, barley, oats, and rye conducted at the station.

Manuring wheat in dry country (*Agr. Gaz. New South Wales*, 11 (1900), No. 11, pp. 1008-1011).—A series of opinions on the subject by wheat growers in the arid districts of Australia.

The reasons for the low yield of wheat in recent years (*Braunschweig Landw. Ztg.*, 69 (1901), No. 2, pp. 7-10).—A discussion of the subject at a meeting of the Central Agricultural Society of the Province of Braunschweig.

HORTICULTURE.

Utilizing the greenhouse in summer, F. W. RANE (*New Hampshire Sta. Bul.* 76, pp. 135-143, figs. 9).—A brief account is given of growing tomatoes, muskmelons, celery, cucumbers, sweet potatoes, eggplant, and peppers under glass in summer.

With tomatoes the varieties Early Acme, Beauty, New Liberty Belle, Ignotum, Fordhook First, and Bond Early Minnesota were used. Picking began about July 10, and lasted a month before the field varieties were ripe. The yield of the tomatoes grown in the greenhouse averaged 2 lbs. 6½ oz. per square foot, and the average price between July

10 and August 10 was 7 cts. per pound, thus giving a money value of 16.8 cts. per square foot. The vines continued bearing until August 30. At this date the average yield per plant was 5 lbs. $3\frac{1}{2}$ oz. per square foot, and the selling price per pound brought the money value up to 20 cts. per square foot.

Peppers were not fruited out of doors. Under glass the large squash pepper yielded at the rate of $160\frac{1}{2}$ lbs. per square rod, and Ruby King at the rate of 122 lbs. per square rod.

Eggplants gave an average return of about 18 cts. per square foot. Early Long Purple gave the quickest returns and was very productive. New York Improved stood next in value.

Celery was easily grown, but there was considerable difficulty in blanching without rotting. The Golden Self Blanching was of most value for indoor culture.

Muskmelons were started in pots and handled similar to cucumbers. It required about 3 months from the time the plants were transplanted into the beds until the fruit matured. Varieties successfully grown were Rose Gem, Netted Gem, and true Jenny Lind.

From the results of the author's experiments with these different vegetables, it is believed that owners of greenhouses can ill afford to allow the house to remain idle throughout the summer. This is believed to have special application to the New England States and those in temperate sections.

The growing of lettuce with chemical fertilizers, W. STUART (*Indiana Sta. Bul.* 84, pp. 115-142, charts 3).—Previous experiments (E. S. R., 11, p. 342) are reviewed and details given of further work to determine the comparative efficiency of chemical fertilizers and stable manure, relative availability of liquid chemical manures when applied to the surface of the soil and from below, and a comparison of surface *v.* subwatering for lettuce. The tests were made in pots, and the results are tabulated and discussed. The author summarizes the results of the present and earlier tests as follows:

"In order to study the action of the three essential elements of plant food—nitrogen, phosphorus, and potassium—a soil must be used that is fairly deficient in plant food. Potash when used in any considerable amount, either alone or in connection with nitrate of soda, produced conditions unsuitable to plant growth. When phosphoric acid was used alone or in connection with nitrate of soda or muriate of potash, even in large amounts, a marked increase in the growth of the plants was obtained. The muriate of potash proved somewhat superior to the sulphate, the increase in each case being but slight. But little difference seems to obtain in the efficiency of different forms of available phosphoric acid. In each instance chemical fertilizers proved slightly superior to stable manures. The application of liquid fertilizers from below by the subwatering method proved perfectly feasible and gave satisfactory results. Nitrate of soda gave quicker returns than did dried blood, and seems best adapted to lettuce culture. The subwatered plants made a better growth than the surface-watered ones."

Methods of apple cultivation on light porous soil, R. GOETHE and E. JUNGE (*Ber. K. Lehranst. Obst, Wein u. Gartenbau, Geisenheim, 1899-1900, pp. 13-15*).—The soil in this experiment was so porous that week-long continued rain was not sufficient to make it too wet. The orchard was divided into sections and treated as follows: (1) Irrigated 4 times with kitchen slop water; (2) the surface soil cultivated, thoroughly forming a loose mulch; (3) blue lupines grown, which were mowed during the summer and left on the ground for the purpose of preserving soil moisture; and (4) soil removed 3 cm. deep over an area of 12 square meters and piled in a ridge about the tree forming a dam for the preservation of all snow and rain water. No other cultivation was given. Another parcel was seeded to vetch. The control plat was spaded in the spring and hoed once during the summer, as is the custom in the locality.

Trees on parcel 1 made a good healthy growth and the fruit developed well. Equally as good results were secured on parcel 2, where the moisture was retained by thorough cultivation. On plats 3 and 5, which were seeded with blue lupines and vetch, respectively, the tree growth was poor and the fruit remained small and dropped early to the ground. The small amount of snowfall did not permit of a thorough test of the value of the earth dam about trees in parcel 4. The trees on the control plat were behind the trees grown on parcels 1 and 2 in every respect.

The essentials of peach culture, J. H. HALE (*Rural New Yorker, 60 (1901), No. 2658, pp. 1, 2, fig. 1*).—The soil and the tree and its care are considered. The author advises the use of trees 5 to 6 ft. high and $\frac{3}{4}$ in. in diameter for planting. The top is unimportant, but there should be a heavy root and a strong cane 15 or 18 in. up. The author has been most successful in planting trees 13 ft. apart each way, or less. Such close planting requires much pruning and for general planting 18 to 22 ft. apart each way is advised. In the South closer planting than in the North may be observed. Catch crops should not be planted in the young orchard, but instead 12 to 15 good cultivations given.

During the first 2 years, after a month or 6 weeks of thorough cultivation, cowpeas may be seeded over two-thirds the space between the rows, leaving space each side of the trees for single-horse cultivation for 2 months more. The pea vines should be left in the ground over winter as a mulch. After the first 2 years, the whole space between the rows should be cultivated up to the last of July or first of August, and then seeded completely with 15 or 20 lbs. of clover for winter protection of the peach roots. The clover should be plowed under in the early spring before much growth takes place.

In pruning a light open head is desired. The first season's growth should not be shortened too much, but the second season all the strong-

est branches may be liberally shortened, leaving the side branches to spread so as to make a broad low head. In case it seems best not to cut a leader entirely away, never cut back to a dormant bud, but always to some side branches; these will slowly take on growth and fruiting strength and check the upward tendency of growth that is sure to follow the cutting back of a strong peach limb to a dormant bud. Not much attention need be paid the side branches; they will never make leaders, and in the author's opinion it is a mistake to do so. A tree pruned as here suggested should give three-fourths of its fruit near enough to the ground so that it can be gathered without a ladder.

Winter irrigation of orchards, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1900, pp. 162, 163*).—Previous experiments along this line have been continued (E. S. R., 11, p. 847). Water was withheld from orchards heavily irrigated during the winter, from June to December, and irrigated again from December to March. The March irrigation was followed by plowing and harrowing and the orchard harrowed again after two slight showers in April to break up the crust that formed over the surface.

"Though having passed through the driest hot period of which there is a record in the valley, the trees are now (July) in the best of condition. The apricot trees have made a young growth of 3 to 6 ft., and the peach trees a growth of about 4 ft. The apricot trees all matured a good crop of fruit, and many of the peach trees are unusually heavily loaded."

A peach and apricot orchard was sown to clover during October and from then until April was irrigated sufficiently to keep the crop growing well. Samples of soil in this orchard taken to a depth of 33 ft. showed that it had been wet to as great a depth as in an adjoining orchard in which nothing had been sown. The results of these experiments are believed to prove "that green manuring and winter irrigation may go hand in hand to excellent advantage."

Growing and grafting resistant vines, F. GILLET (*Pacific Rural Press, 61 (1901), No. 8, p. 116*).—The author reports his experience in bench grafting resistant stock. The best results have been obtained on Riparia. One or two year old rooted cuttings are used in preference to plain cuttings because of a gain of one year in time, and because a larger percentage will grow. In field practice the author used rooted cuttings just grafted and rooted resistant stock in alternate rows. While succeeding with 85 to 90 per cent of the former, only 60 per cent of the grafts of the latter grew, and these produced hardly any grapes that year, while on the former from 8 to 11 lbs. per plant were secured. On the whole, bench grafting resistant vines is considered the best, cheapest, and quickest way of reconstructing a vineyard or starting a new one.

Fertilizer experiments with nitrate of soda in the red wine district of the Ahr Valley (*Ber. K. Lehranst. Obst, Wein u. Gartenbau, Geisenheim, 1899-1900, pp. 103-107*).—Experiments were made

in different mountainous districts to determine the influence of nitrate of soda on grapes and the effect of early and late applications. The soil was naturally well supplied with mineral matter. The nitrate was applied at the rate of 300 kg. per hectare. It was especially effective on the steep hillsides. Its influence was noticeable in the greater wood growth, the larger size of the fruit, and the darker green of the leaves. The leaves also hung on the vines about two weeks longer than where no nitrate was used. Even late applications of nitrate of soda produced no harmful effects. The good effect of the nitrate was not so noticeable in rich, humus, clay soils in the valleys. The must from the fertilized and unfertilized plants showed no essential difference in specific weight, sugar or acid content, and the wine was similar in chemical character. There was considerable difference, however, in the nitrogen content of the wine, that from the fertilized vines being 10 per cent higher than that from the nonfertilized vines. The leaves of the fertilized vines were likewise richer in nitrogen.

In conclusion, the author states that no harmful influence whatever could be detected from the use of nitrate of soda, even with late applications. Wherever differences were noticeable they were always in favor of the nitrate.

Gardening in Germany, L. WITTMACK (*Gartenflora*, 50 (1901), Nos. 2, pp. 38-44; 3, pp. 70-74; 4, pp. 94-96).—The historical development and present status of vegetable, flower, and fruit gardening in Germany is considered, some statistics on seed production, fruit imports and exports, cut-flower and plant production being included.

Vegetables, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1900*, pp. 158-161).—Cultural notes and the results of tests of varieties of cabbage, lettuce, watermelons, onions, and cauliflower. Succession, Fottler Brunswick, Large Late Drumhead, and All Seasons cabbage gave the heaviest yields per acre. New York and Tyrol produced the largest heads of lettuce. Of the watermelons tested Augusta proved the most satisfactory. In the culture experiments with onions slightly better results were secured when the plants were sown in place and thinned than when they were transplanted. The variety Prize Taker gave the heaviest yield and produced the best quality of onions.

Asparagus culture, E. LESSER (*Landw. Wechnbl. Schleswig-Holstein*, 51 (1901), No. 5, pp. 82, 83).—Method of culture and best varieties are considered.

Forcing haricots, C. POTRAT (*Belg. Hort. et Agr.*, 13 (1901), No. 1, pp. 7, 8).—Cultural directions for growing kidney beans in the forcing house.

Tropical species of Mucunas and Dolichos, E. ANDRÉ (*Rev. Hort.*, 73 (1901), No. 3, pp. 61-63, figs. 5).—The author states that these plants are the beans of warm countries. *Mucuna pruriens*, *M. nirea*, *M. gigantea*, *M. horrida*, *M. utilis*, *M. atropurpurea*, and *M. monosperma* are briefly characterized and *M. pruriens* and *M. nirea* illustrated.

The cultivation of Znaim cucumbers, J. G. SMITH (*U. S. Dept. Agr., Section of Seed and Plant Introduction Circ.* 2, pp. 4).—Notes are given on the culture and cost of production of cucumbers at Znaim, Austria. The Znaim cucumbers are a variety of *Cucumis sativus*, and are extensively cultivated for export as pickles, salted, spiced, preserved in sugar, or flavored with mustard. The seed of this cucumber has been obtained for distribution among the agricultural stations of the country.

American ginseng, M. G. KAINS (*Amer. Gard.*, 22 (1901), No. 325, pp. 188, 189).—Abstract of an address before the Horticultural Society of New York, March 13, 1901.

The best horse-radish varieties of Europe, and methods of cultivation, D. G. FAIRCHILD (*U. S. Dept. Agr., Section of Seed and Plant Introduction Cir. 1*, pp. 8, figs. 4).—Methods of growing Bayersdorf and Maliner Kren or Bohemian horse-radish are here described in detail and estimates given as to the cost of production and the profits in horse-radish growing.

Lettuce forcing, W. SCOTT (*Amer. Gard.*, 22 (1901), No. 324, p. 171).—Methods based on experience. Grand Rapids has been found easiest to grow and least subject to disease of the open types, and Deacon has proven the most satisfactory of the head lettuces.

Prospects and present condition of agave culture in German East Africa, R. HINDORF (*Tropenpflanzer*, 5 (1901), No. 1, pp. 1-17).

The relation of growth to flowering in fruit trees, E. S. GOFF (*Amer. Gard.*, 22 (1901), No. 319, p. 75).—The principles are laid down by the author that (1) there is an inverse relation between growth and flowering—the causes that promote growth being opposed to flowering and *vice versa*; (2) “that the amount of growth that takes place in any part of a plant depends upon the amount of water received by that part, and (3) that flower buds form freely only when they receive an abundance of light.”

On fertilization of fruit trees, M. WEIBULL (*Landtmannen*, 11 (1900), No. 21, pp. 338-343).

Fruit culture for northern latitudes, J. H. HALE (*New Hampshire Bd. Agr. Rpt. 1899-1900*, pp. XXI-XXXIX).—Refers especially to New England and New England conditions.

New hardy fruits for Manitoba and the Northwest Territories, W. SAUNDERS (*Ontario Fruit Growers' Assoc.*, 1899, pp. 109-113).—*Pyrus baccata* was crossed in 1894 with several varieties of hardy apples, such as Tetofsky, Wealthy, and Duchess. From the seeds obtained, seedlings were grown, five of which seem to be of much merit and are described. Crosses have also been made on *Pyrus prunifolia*, but no fruits have been obtained as yet.

Report of the fruit experiment stations of Ontario, L. WOOLVERTON ET AL. (*Ontario Fruit Expt. Stas. Rpt. 1899*, pp. 68, figs. 38).—Results are reported of cultural and variety tests of orchard and small fruits at 13 fruit experiment stations in Ontario. Descriptions and illustrations are also given in addition to those previously noted (*E. S. R.*, 11, p. 547) of 5 varieties of apples, 9 of cherries, 2 of peaches, 4 of raspberries, 2 of pears, and 1 each of currants, grapes, and plums grown in Ontario.

The production of high-grade fruit, G. E. POWELL (*Ontario Fruit Growers' Assoc. Rpt. 1899*, pp. 32-47).—The author is meeting with success in topworking Northern Spy stock with scions from well-formed and bearing Kings. The method of orchard cultivation observed by the author is also described.

The effect of yearly pruning on the growth of orchard trees (*Ber. K. Lehranst. Obst, Wein u. Gartenbau, Geisenheim, 1899-1900*, pp. 18-21).—Numerous observations go to show that yearly pruning hinders the growth of the tree and greatly retards the blooming period.

The apple in West Virginia, L. P. MILLER (*West Virginia Farm Rec.*, 8 (1900), No. 12, pp. 396-399).—The sorts and location for apple orchards in West Virginia are discussed. Freestone and soapstone highlands with trees 40 by 40 ft. apart are advocated.

Notes on some of the newer apples, G. B. BRACKETT (*Amer. Gard.*, 22 (1901), No. 325, pp. 190, 191).—Historical and descriptive notes on York Imperial, Arkansas, Paragon Beach, Collins Red, Oliver, Reagan, Stayman Winesap, Grimes Golden, Jonathan, and White Pippin.

Newton Pippin hybrids in New York (*Amer. Gard.*, 22 (1901), No. 322, p. 134).—Notes on Newton Pippin hybrid apples grown on selected seedlings from Newton Pippin crossed on Northern Spy, Rhode Island Greening, and Russets. The hybrids are believed to be very important additions to our list of apples.

International fruit exhibit at Paris (*Württemberg. Wechnbl. Landw.*, 1900, No. 47, p. 739).—A comparison of American and German apples.

Mineral constituents of apples and pears, E. HOTTER (*Ztschr. Landw. Versuchs. Oesterr.*, 3 (1900), No. 5, pp. 583-585).—A table is given showing the summarized ash analyses of the fresh and dry substance of several varieties of apples and pears.

The pear tree—study of its method of fructification, C. TRÉBIGNAUD (*Jardin*, 14 (1901), No. 332, pp. 380-382, figs. 1).—The variety Passe-Crassane was studied especially.

Essential principles of pear culture in the Hudson River Valley, J. R. CORNELL (*Rural New Yorker*, 60 (1901), No. 2667, p. 163).—The author advises the use of only standard trees set 20 ft. apart each way. Phosphoric acid, potash, and crimson clover are the fertilizers used. The most desirable varieties are Elizabeth, Bartlett, Seckel, and Bosc, mentioned in the decreasing order of their importance.

Pruning in place of thinning (*Pacific Rural Press*, 61 (1901), No. 9, p. 129).—Spring pruning peaches after the fruit had set was compared with winter pruning and the fruits thinned by hand. The spring pruned peaches were larger than the winter pruned, and the conclusion is reached that spring pruning can replace winter pruning and thus save the cost of hand thinning.

Report of the horticulturist, H. H. HUME (*Florida Sta. Rpt. 1899 and 1900*, pp. 25-30, figs. 3).—A brief account of citrus experiments under way, pecan culture in Florida, and on 3 native plants for decorative purposes. Fifty navel and sweet oranges have been budded on 5 different kinds of stock, viz, pomelo, sour orange, rough lemon, sweet orange, and *trifoliata*, to determine to some extent the relative merits of these stocks. Descriptions and illustrations are given of the Atamasco lily (*Zephyranthes atamasco*), sparkleberry (*Vaccinium arboreum*), and sumac (*Rhus copallina*), native plants believed by the author to be of value for ornamental purposes.

Heating lemon orchards (*Tradesman*, 44 (1901), No. 12, p. 62).—This is an account of an experiment with artificial heat for preventing damage from frost in a large lemon orchard near Santa Paula in California. It is reported that by means of small coal fires in iron baskets placed at different points in the orchard the latter was protected from injury, although the normal temperature of the valley fell as low as 22° and heavy frost was formed in fields surrounding the orchard.

The artificial coloring of oranges, PUM and K. MICKO (*Ztschr. Untersuch. Nahr. u. Genussm.*, 3 (1900), No. 11, pp. 729-735, pls. 2, fig. 1).—From numerous experiments the author shows that the artificial production of blood oranges must be very limited. The chemical composition of the coloring matter of the juice of true blood oranges was also studied.

Report of the instructor in coffee culture, H. NEWPORT (*Queensland Dept. Agr. Rpt. 1899-1900*, pp. 38-41).—A general discussion of coffee culture in Queensland.

Liberian coffee, its culture and preparation for market, V. BOUTILLY (*Le caféier de Libéria, sa culture et sa manipulation*. Paris: Callamel, 1900, pp. VII+140).

American tea gardens, actual and possible, LENORA B. ELLIS (*Amer. Mo. Rev. of Rev.*, 23 (1901), No. 3, pp. 315-320, figs. 8).—The article is based on the results secured at Summerville in South Carolina on the Pinehurst estate, an account of which has been noted elsewhere (E. S. R., 11, p. 741).

The influence of copper compounds on the phenomena of ripening, CHUARD and F. FORCHET (*Rev. Vit.*, 14 (1900), p. 75; *abs. in Ann. Agron.*, 26 (1900), No. 11, pp. 577, 578).—Copper salts in solution were sprayed on currants to observe their effects on the ripening of the fruit. The copper treatment increased regularly, but only in a small way, the size of fruits and also their sugar content. This increase did not exceed 1 to 2 per cent.

Cost of growing cranberries, A. J. RIDER (*Proc. Amer. Cranberry Growers' Assoc.*, 1900, pp. 5-8).—The cost of growing, harvesting, and marketing a bushel of cranberries is estimated at \$1.55.

Strawberry culture, A. DESPEISSIS (*Agr. Jour. Cape Good Hope*, 18 (1901), No. 2, pp. 74-90).—Strawberry classification, mulching, propagation, picking, and packing, descriptions of varieties of different classes, and methods of protection against insects and diseases are discussed at length.

Report of strawberries on the strawberry valley farm for the summer of 1900, E. W. WOOSTER (*Amer. Gard.*, 22 (1901), No. 322, p. 129).—This farm is located at South Hancock, Me. The season was dry. Clyde resisted drought well. Brandywine gave better results on plants of the second and third year fruiting. Hunn was the latest variety ever grown on the farm. Of the new berries Dewey outranked every other variety grown in desirable qualities. Hawaii was the earliest berry fruited, of excellent quality, and especially desirable for home use.

California raisin culture (*Sci. Amer.*, 84 (1901), No. 1, pp. 3, 8, figs. 8).—Popular account of the industry.

Test of the Sutherland fruit preserving process, G. QUINN (*Rpt. Min. Agr., South Australia*, 1900, p. 37).—By this process the individual fruits (except grapes) are wrapped in tissue paper and packed in damp-proof waxed paper bags, which fit as a lining in the fruit cases. After the fruits are packed, the mouth of the bags is folded over and a hot iron passed along the folded edge. This melts the wax and seals the opening air-tight. The cases are then closed and placed in a temperature 1 or 2° above freezing. Tests are reported with pears, peaches, and grapes, but as there was only one check lot the test is considered incomplete. The check lot showed no disadvantage because of the omission of the waxed paper.

Home or farm canneries, D. S. HELVERN (*Missouri State Hort. Soc. Rpt. 1900*, pp. 75-77).—The author describes his small canning plant, which is proving a valuable adjunct to the farm.

The cactus and decorative dahlias, S. MOTTET (*Jardin*, 14 (1901), No. 331, pp. 360-364, figs. 4).—Notes on the different races and descriptions of varieties.

Subwatering carnations (*Florists' Exchange*, 13 (1901), No. 10, pp. 243, 244).—In a discussion of this subject at a meeting of the American Carnation Society, J. L. Dillon stated that he used solid beds made of 1 part Portland cement and 5 parts coal ashes. The beds were filled first with 3 in. of coarse screened ashes. On top of this was put 1 in. of fine ashes and then 4 in. of soil. Water was run into a round tile which connected with V-shaped tile running across and lengthwise of the bed. The beds were watered 4 or 5 times more quickly by this method than by surface watering, and about 25 per cent more and better flowers were obtained.

Hybridizing the carnation, P. FISHER (*Florists' Exchange*, 13 (1901), No. 8, pp. 189, 190).—Paper read by the author before the American Carnation Society at its Baltimore meeting, February 21, 22, 1901.

History of chrysanthemums, C. CHEVALIER (*Belg. Hort. et Agr.*, 12 (1900), No. 23, pp. 354, 355; 13 (1901), No. 1, pp. 6, 7).—Historical notes on the chrysanthemum in Europe.

New researches on Persian lilacs and their crosses, L. HENRY (*Rev. Hort.*, 73 (1901), Nos. 2, pp. 39-42, figs. 3; 3, pp. 60-72, figs. 6; 4, pp. 93-95, figs. 3).—Largely of a historical nature.

The newer roses, E. G. HILL (*Florists' Exchange*, 13 (1901), No. 11, pp. 264, 265).—Paper on the subject read by the author before the New York Florists' Club, March 11, 1901.

The question of color relative to flowers, F. S. MATHEWS (*Florists' Exchange*, 13 (1901), Nos. 5, p. 110, figs. 4; 10, Sup.).—The author presents a scheme for the scientific building up of a nomenclature for colors in flowers founded on the simple range of the prism.

FORESTRY.

Experiments in replanting cut-over pine lands, H. H. CHAPMAN (*Farm Students' Rev.*, 6 (1901), No. 1, pp. 6, 7). —An account is given of cooperative experiments with the Division of Forestry of this Department, in which pine seedlings were transplanted in the spring of 1900 on cut-over pine lands at the Northeast Experiment Station of Minnesota. White and Norway pines were the principal varieties used. Different distances of planting were compared, and also the effect of alternating the varieties in rows and planting alternated rows of jack pine. The pines were dug from the nursery rows, covered with dirt until loaded into the wagons, and the whole mass wet by throwing water over it. The planting was commenced as soon as the ground had thawed to a spade's depth. The first plantings were made by cutting the turf on each side with a spade, turning up the turf and soil and inserting the roots of the plant, no particular effort being made to separate or arrange them. Later, when the ground became drier, the top layer of roots and sod was turned back and a spadeful of dirt from below was placed over the roots before the sod was replaced. A dry season followed, and, contrary to expectations, the loss was less than 5 per cent. In all more than 13,000 trees were planted at a cost ranging from \$2 to \$11 per acre, dependent upon the distance planted. The trees at the time of planting were rather large for pine seedlings, and the cost is considered rather more than the average cost of planting on a large scale.

Norway spruce for profit on the plains, H. B. KEMPTON (*Forester*, 6 (1900), No. 12, pp. 295, 296). —The Norway spruce, which is comparatively well known in the eastern United States, is said to have been planted but little upon the plains. It has been sufficiently introduced, however, to show its adaptability over a wide range of that country. It seems probable that it is adapted to a large part of Iowa, Nebraska, Kansas, and other central western States. An account is given of the planting made at Conroy, Iowa, 18 years ago. The seedlings were secured at Mount Carroll, Ill., and packed closely in wet sphagnum moss. When received they were still moist, and were set in nursery rows. For several years they were screened by a partial shade of lath, after which they were transplanted in 12-ft. rows set 4 ft. apart in the row, and were interplanted with corn. Not less than 95 per cent of the seedlings are alive at the present time and in good condition. Growing nearby are plantations similarly managed of green and white ash, box elder, soft maple, honey locust, red cedar, white and Scotch pine; and under the conditions existing the Norway spruce has made more rapid growth than any of the other trees. The growth of the Norway spruce trees on this plantation has averaged 1 ft. 9 in. for the past 15 years, the present height being 29 ft., with

an average diameter of 4.7 in. In 10 years from now it is calculated that the poles will be worth \$258.16 more than would have been secured from the market price of corn cultivated for the same time on the same area.

Additional notes on tree measurements, C. E. HALL (*Trans. and Proc. Bot. Soc. Edinburgh*, 21 (1900), pt. 4, pp. 243-258).—In the transactions of this society for 1890 (vol. 18, p. 456), the author reported upon the rate of growth of a number of trees from measurements made at San Jorge, Uruguay. Monthly measurements of these trees have been made from January, 1885, to January, 1900. Sixteen trees were measured—2 eucalyptus, 2 stone pine, 2 blackwood (*Acacia melanoxylon*), 2 oaks, 3 *Melia azedarach*, 2 Lombardy poplars, 1 robinia, 1 maple, and 1 cottonwood. The increments in tree growths are shown in tabular form and comments given upon the causes of the variation in some specimens. The growth of the trees during the period between 1890 and 1899 is shown in the following table:

Growth of trees during nine years at San Jorge, Uruguay.

Kind of tree.	Circumference of tree.		Increased growth of tree.	
	January, 1890.	January, 1899.	Total.	Annual.
	Mm.	Mm.	Mm.	Mm.
<i>Eucalyptus</i> sp.	774	1,746	972	108
Do.	725	1,491	766	85
<i>Pinus pinea</i>	1,141	1,559	418	46
Do.	980	1,467	487	54
<i>Acacia melanoxylon</i>	727	932	205	23
Do.	989	1,460	471	54
<i>Melia azedarach</i>	609	792	183	20
Do.	602	768	166	18
Do.	1,446	1,632	186	21
<i>Quercus robur</i> (?)	492	872	380	44
Do.	572	814	242	27
<i>Populus fastigiata</i>	809	1,008	199	22
Do.	704	865	161	18
<i>Populus angulata</i>	755	1,375	620	67
<i>Robinia pseudacacia</i>	433	536	103	11
<i>Acer pseudoplatanus</i>	670	1,055	385	43

The author also shows the monthly rate of growth, from which the effect of growing season and dormant period may be seen.

Forest planting, W. GILL (*Ag. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1130-1132, figs. 7).—The 2 methods by which young trees are planted in South Australia are termed the "open root" and "bamboo tube" systems. The open root system consists of growing the trees in the open ground in nurseries, from which they are transplanted by the usual method. Unless the young trees are carefully protected, to prevent the drying out of the roots, many failures in planting will result. The bamboo tube system, which consists of growing the plants in small sections of the bamboo and setting them out in this way, is in many respects preferable. This method is practiced very largely in the propagation of gum trees, it having been found by far the best and most economical, as well as proving safer so far as root exposure is concerned.

Eucalypts, A. J. McCLATCHIE (*Arizona Sta. Rpt. 1900*, pp. 165, 166).—A report is given of the experiments which have been conducted with the different species of *Eucalyptus* at the Arizona Station. Of a large number of species that have been tested many have been found to have been unable to withstand the summer temperatures of that region. Others have been found exceedingly valuable for planting and some of these are rated among the most valuable species of the genus. The species which have survived the heat and dryness of the Territory are *Eucalyptus corynocalyx*, *E. cornuta*, *E. hemiphloia*, *E. leucoxyton*, *E. melliodora*, *E. occidentalis*, *E. polyanthema*, *E. rostrata*, *E. rudis*, and *E. tereticornis*.

The Carolina poplar, J. T. ROTHROCK (*Forest Leaves*, 7 (1900), No. 12, pp. 184, 185, pls. 2).—A description is given of the Carolina poplar or cottonwood (*Populus monilifera*). This tree frequently attains the height of 100 ft., with a diameter of 7 or 8 ft. The tree is described at some length, and on account of its rapid growth and adaptation to all kinds of soils is said to be a promising one for forest culture. The wood is brittle, liable to split and warp, but is valuable for the production of wood pulp. On this account it is likely to exceed other native trees for such purposes. An account is given of a planting made in 1899 of 1,000 cuttings of the Carolina poplar which, without any protection during the winter or especial preparation when planting, presented 75 per cent of the plants making satisfactory growth the following year.

SEEDS—WEEDS.

The protein substances of seeds, T. BOKORNY (*Bot. Centbl.*, 82 (1900), No. 10-11, pp. 289-306).—The present state of our knowledge of the protein substances of seeds is summarized by the author, in which it appears that globulins soluble in 5 to 10 per cent solution of sodium chlorid are stored up in the protein grains and albumin crystals of seeds. The protein or aleurone grains vary in size from 1 to 55 μ , their largest size being obtained in oily seeds. In the endosperm of cereals they are said to be very small but never entirely absent. The presence of active protein could not be detected in grains. The fibrin of cereals is said to be peculiar in that it is soluble in 70 to 80 per cent cold or hot alcohol, a reagent which precipitates the other protein substances. The author was unable to detect any peptone in dormant seeds, while albumoses were occasionally found in minute quantities. Amid substances, such as asparagin, tyrosin, and leucin, are widely distributed in seeds and the vegetative parts of plants. The author states they appear to be the first products of decomposition and the first stage in the formation of protein substances.

The influence of the sun's rays upon the germination of seeds, T. TAMMES (*Landw. Jahrb.*, 19 (1900), No. 3, pp. 467-482, pl. 1).—The effect of the sun's rays upon the germination of sunflowers, horse beans, centaury, rice, *Allium fistulosum*, *Erodium cicutarium*, and *Nicotiana rustica* is shown. The experiments were conducted with specially devised apparatus in which comparisons could be made of seeds germinated under identical conditions except as to illumination. One lot was germinated entirely in the dark, another received direct sunlight for 44 days, while the control lot was germinated out of the

direct rays of the sun. In nearly every instance those seeds which were subjected to the direct sun's rays were retarded in their germination, although the effect upon the total germinative ability was not influenced in any appreciable degree, the total number of germinations in each lot being practically the same.

On the germination of tobacco seed, M. RACIBORSKI (*'S Lands Plantentuin, Bul. Inst. Bot. Buitenzorg, 1900, No. 6, pp. 10*).—The wide variation presented by the germination in different lots of tobacco seed, when tested under varying conditions, led the author to investigate some of its causes. Similar lots of seed were germinated under identical conditions except that one lot was kept in total darkness and the other in diffused daylight. The seed placed in the light germinated rapidly and well, while those kept in the dark, although the investigations were continued for 40 days, in some cases did not show a single germination. Submitting the latter to the light for a few hours, however, was sufficient to stimulate the seed to germination. Tobacco seed sown upon soil, sand, peat, etc., and kept in the dark, failed to germinate.

The effect of age on seed was investigated, with the result that 1-year-old seed germinated 96 per cent, 2-year-old 85 per cent, and 4-year-old 66 per cent. The variation due to variety was tested, in which it was found that tobacco seed varied from 1 to 10 per cent in different varieties when germinated under identical conditions. Notes are given on some of the physiological phenomena during germination, and chemical studies on the differences between the roots and the stems of the young plantlets.

Germination of wheat and oats treated for smut (*Wyoming Sta. Rpt. 1900, pp. 3*).—A report is given of the effect on germination of treating wheat and oats with solutions of copper sulphate, potassium sulphid, and by the Jensen hot-water treatment. The copper sulphate solution was made by dissolving 1 lb. of commercial copper sulphate in 24 gals. of water. In these the seed were soaked 13 hours, after which they were removed and immersed in linewater for 5 minutes. The potassium sulphid treatment consisted of soaking the seed for 2 hours in a 2 per cent solution of that substance. The hot-water treatment consisted of subjecting the seed grain to a temperature of 135° F. for 15 minutes. The results of the germination test showed that in every case the treatment proved injurious to the seed. As a possible explanation of this fact it is suggested that the seed coats of the grain, nearly all the specimens of which had been grown at Laramie in 1899, may have been much thinner than usual, thus not offering the protection usually given to such seeds.

Combating weeds by means of metallic salts, FRANK (*Arb. K. Gesundheitsamte, Biol. Abt., 1 (1900), No. 2, pp. 127-175, pl. 1*).—A review is given of some of the literature relating to the destruction of

weeds by chemical means, and a detailed description of the author's experiments made in 1899 to determine the best chemicals and the quantities required for their destruction. The method of application, whether in the form of a solution or powder, was also investigated. From the results of his experiments the author states that iron sulphate in 15 per cent solutions, at the rate of 500 liters per hectare, gave the most satisfactory results, when cost of materials and efficiency were considered. Copper sulphate in a 5 per cent solution, at the same rate, was equally efficient, but was more expensive. The method of application showed decidedly in favor of spraying with solutions. In addition to the effect of the solutions upon the weeds, the amount of injury to crops in which the weeds were growing was noted and reported. The crops sprayed with the herbicides were oats, barley, wheat, rye, red clover, peas, vetches, potatoes, and sugar beets.

The author sums up his observations with the statement that spraying with metallic salt solutions must not be considered as a universal means for weed destruction. The solutions killed wild mustard and wild radish, and seriously injured curly dock, black bindweed, dandelion, sow thistle, and senecio, but had little or no effect on the poppies, chenopodiums, euphorbias, cornflower, field thistle, chamomile, bindweed, couch grass, bent grass, or equisetums. Little or no injury to field crops was observed when the solutions were sprayed over cereals, red clover, or sugar beets, the plants readily recovering from the slight injury inflicted. Field peas were considerably affected, and vetches and potatoes badly injured. The best time to spray for the destruction of charlock and mustard is when the plants are from 4 to 7 cm. high, or about the time the plants have 3 or 4 leaves, and before they begin to flower.

Red clover seed, A. J. PIETERS (*U. S. Dept. Agr., Farmers' Bul. 123, pp. 11, figs. 2*).—Red clover seed and its more common adulterants and mixtures are described and notes are given showing the results of tests made of different samples of clover seed. The pure and germinable seed in the samples ranged from 53.26 per cent to 95.8 per cent. The calculated price of the different lots reported upon varied from \$4.74 to \$9.00 per bushel. Field tests of a number of American and European clovers are briefly reported upon. Thirty-five samples of European and American clovers were sown in plats 1 rod square. The sowings were made the latter part of April and the condition of the plants throughout the season is indicated. At the end of June the average condition of the European plats was slightly better than that of the American, but from that time on there was a decided change to the advantage of the American grown seed. The effect of the summer heat was very injurious to the European varieties. In July and September all the plats were mown, the green fodder weighed and the amount calculated per acre. The average yield of green clover for the season, from the American seed, was 12,704 lbs., and the European 7,792 lbs.

Report of seed testing, BAESSLER (*Ber. Agr. Chem., Vers. u. Samencontrol Sta., 1900, pp. 14-16*).—A report is given upon the testing of 1,085 samples of seeds, an increase of nearly 50 per cent over the previous year. Especial attention was given the presence of dodder seeds in clover and grass seeds. Dodder seed was found in

more than half the samples of red clover, alsike clover, white clover, alfalfa, and timothy. The average purity of all samples examined showed a depreciation of 0.5 per cent from that of the previous year.

Potassium perchlorate poisoning and its prevention, J. R. JUNGNER (*Deut. Landw. Presse*, 27 (1900), No. 62, p. 111, figs. 2).—Germination experiments to study the physiological effects of the perchlorate are reported.

The weeds of Ontario, F. C. HARRISON (*Bul. Ontario Dept. Agr.*, 1900, Mar., pp. 80, figs. 34).—Popular notes are given on the introduction and spread of weeds, means for their identification, and suggestions for eradication. A number of the more common weeds are figured and described, and specific directions for their eradication are given so far as possible.

Destruction of mustard with ammonium sulphate, G. CASTEL-DELÉTREZ (*Jour. Roy. Agr. Soc. L'Est Belg.*, 1900, p. 112).

The destruction of certain weeds, as ground ivy, mustard, and thistles, by spraying with a solution of metallic salts (*Deut. Landw. Presse*, 27 (1900), No. 27, pp. 327-329, figs. 6).

The eradication of lantana (*Indian Forester*, 27 (1901), No. 1, pp. 28-33).—Lantana is said to have been introduced into India as a hedge plant some 40 years ago, and it has spread widely, until in some districts it has become a very serious pest. An account is given of various experiments conducted for its eradication. In Ceylon it was found that lantana which had thickly occupied the ground for 12 or more years, could be cleared by contract at the rate of about \$7.50 per acre, the plants being uprooted and burned. Detailed accounts are given of experiments in eradication in a number of parts of India, from which it appears that dense growths of this pest may be eradicated at a cost of about \$7.50 per acre, which includes the original clearing and 3 seasons of subsequent work.

DISEASES OF PLANTS.

A preliminary bulletin on the prevention of smut on oats, E. F. PERNOT (*Oregon Sta. Bul.* 63, pp. 9). A preliminary report is given of a series of experiments to prevent the smut on oats, in which seed were treated with solutions of copper sulphate and zinc sulphate, hot water, formalin, and sterilized dry hot air at a temperature of 200° F. for 10 minutes. After treatment the seeds were sown, and at harvest all the oat heads which showed any signs of smut were carefully removed and counted. The least smut was found on the plats the seed of which had been treated with hot water and hot air, the greatest amount of smut occurring on those plats which had received the formalin treatment in which two different strengths of solution were used. The effect of treating oats for 10 minutes at different temperatures of hot air, from 132 to 200°, were tested, in which it was found that none of the treatments seriously affected the germination of the seed. On account of the convenience of handling the oats, the author is disposed to recommend the dry hot air sterilization for smut prevention. An extensive experiment with different seed grains is to be conducted, in which the value of hot air as a preventive of smut is to be further investigated.

Investigations on a leaf curl of mulberry trees, M. MIYOSHI (*Bot. Conthl.*, 83 (1900), No. 11, pp. 346, 347).—This disease, which seriously threatens the mulberry trees of Japan, is characterized by a marked increase in the number of lateral twigs and leaves through the development of adventitious buds. At the same time the development of the leaves becomes abnormal. They are greatly reduced in size, crumpled with a less developed mesophyll, while upon the upper side numerous blister-like elevations occur between the veins. The leaves become yellowish in color and hard in texture, and the twigs are but little developed. In the older branches, where the disease has been severe, leaf and twig growth is stopped and the whole branch ultimately falls to the ground.

The cause of this disease is believed to be not parasitic, but is due rather to the impaired functions of the twigs and leaves, brought about by the common practice of removing them for silkworm feeding.

The "mal nero" of grapes, D. CAVAZZA (*Vigne Amer.*, 24 (1900), Nos. 5, pp. 155-157; 6, pp. 182-186).—This grape disease, which the author says is also known as "bacterial gummosis," the California vine disease, gélivure, chytridiose, etc., is said to be a very polymorphous disease caused by *Bacillus vitivorus*. It attacks all parts of the plant, producing variable symptoms which seem to be somewhat dependent upon external conditions. The season, time of appearance, and development of the parts attacked influence the color of the diseased leaves, making them yellow, red, reddish brown and violet, etc., as the case may be. The bacillus attacks the cambium and extends into the wood of the vine, producing irregularly triangular brown spots. As means for the partial prevention of the disease, which the author believes attacks the plants from the soil, the fumigation of the soil with carbon bisulphid and thorough drainage are recommended.

Copper sulphate as a remedy for grape mildew (*Sci. Amer. Sup.*, 49 (1900) No. 1266, p. 20301).—A report is given of investigations with copper sulphate for the prevention of grape mildew. On account of the solubility of this substance it is claimed that it does not adhere readily to the foliage, and numerous attempts have been made to secure a more adhesive as well as cheaper mixture. The results of some investigations by Trabut are given, in which the dry resin exuded from pines in Algeria, as well as the mucilage which is extracted from the stems of the Barbary fig tree, were used with excellent results. The resin mixtures were prepared by heating 1 kg. with 500 gm. of soda or potassium carbonate. To this was added 500 gm. copper sulphate and 100 liters of water. A second preparation was obtained by extracting by maceration the mucilage from 3 to 5 kg. of the Barbary fig tree and adding simple solution of copper sulphate. By the use of either of these fungicides it is claimed that from 50 to 80 per cent of the copper sulphate is saved and the prevention of the mildew secured.

A sclerotioid disease of beech roots, H. VON SCHRENK (*Rpt. Missouri Bot. Gard.*, 10 (1899), pp. 61-70, pls. 2).—The author reports having found a large number of small tubercles attached to the fibrous roots of beech trees. The tubercles were of various sizes and shapes, some almost round, others elliptical and varying in size from about as large as a small pea to some scarcely visible to the naked eye. Upon examination of the tubercles they were found to consist of a bundle of cylindrical bodies which intertwined. Each was covered and held firmly in place by a membrane or sheath. The main body of the tubercle consisted of a large number of small rootlets, each twisted and contorted and held in place by the fine hyphae. The cause of the formation of these structures is attributed to the stimulus brought about by some fungus. No evidence of parasitism was observed, the hyphae simply surrounding the roots without entering the cells. The presence of a large number of small sclerotia, together with the tubercles, suggests that the sterile mycelium of the tubercles probably belongs to some Hymenomycete which usually forms sclerotia.

Chrysanthemum rust, J. C. ARTHUR (*Indiana Sta. Bul.* 85, pp. 143-150).—The occurrence of rust on chrysanthemums was observed in the fall of 1899 in Indiana. It is easily distinguished from all other diseases that attack the chrysanthemum, as it forms small blisters about the size of a pin head, appearing on the under surface of the leaf. These soon break open and expose a dark brown powder, the uredospores. These blisters by coalescing frequently become of considerable size and are occasionally found upon the upper surface of the leaves. An experimental study was made by the author to infect a number of related species with the uredospores of this fungus, but it was found to grow only upon the true chrysanthemum. The fungus, which is known as *Puccinia chrysanthemi*, appears to be a native of Japan introduced into Europe and America through commercial agencies. Thus far no teleutospores have been found and on this account the disease would probably be of easy control. Picking off the diseased leaves and the total destruction of badly diseased plants, together with spraying with Bordeaux mixture or potassium sulphid will doubtless keep the disease in check.

Concerning the rust fungus on chrysanthemums, P. MAGNUS (*Gartenflora*, 49 (1900), No. 11, pp. 294-296).—The specific causes of the rust growing on *Chrysanthemum indicum* have been examined by a number of individuals and their determinations are given. According to Massee, the fungus is *Puccinia hieracii*. Subsequently, the rusts on chrysanthemums have been investigated by Rozé, who finds them due to different causes, one of which is designated as *Uredo chrysanthemi*. For this form, spraying with Bordeaux mixture seems to have had no effect in preventing diseases. In a later publication, Rozé describes *Puccinia chrysanthemi*, which he says is the cause of the rust on chrysanthemums.

An anthracnose and a stem rot of the cultivated snapdragon, F. C. STEWART (*New York State Sta. Bul.* 179, pp. 105-111, pls. 3).—In 1897 the author's attention was called to an anthracnose of snapdragons occurring in a greenhouse on Long Island, and upon inquiry he learned that it was a rather common disease, being the most destructive of the diseases to which this plant is subject. It attacks the plants at any stage of their growth, in the greenhouse and in the field. In the greenhouse it is most destructive in the fall and spring, while in the fields its ravages are most conspicuous during August and September.

It attacks the stems and leaves of the plants. Upon the stem it produces elliptical sunken spots 3 to 10 mm. in length. Upon the leaves the spots are circular, and have a diameter of from 3 to 5 mm.

The cause of this disease is said to be *Colletotrichum antirrhini*, n. sp., which is described. An experiment was undertaken for the prevention of the disease, in which plants were sprayed once a week with Bordeaux mixture, receiving during the course of the summer 17 applications. In August the contrast between the sprayed and unsprayed plants was very striking, and in September the unsprayed plants were completely ruined while the sprayed ones were in perfect health. As recommendations for treatment the author suggests that cuttings should be made from healthy plants only, and where the disease is troublesome spraying with Bordeaux mixture, beginning as soon as the cuttings are rooted and continuing until the plants are transplanted in the fall. So far as known at present, this anthracnose attacks no other plant, and growers whose grounds are free from the disease will have no trouble so long as they propagate from their own stock or seed.

The stem rot described was first observed in December, 1898. It attacks chiefly the succulent shoots, causing several inches of the terminal portion to wilt and die. In some cases, especially where the shoots have become somewhat woody, a section of the stem turns brown while the portion beyond remains green. In a short time the whole branch dies.

This disease is attributed to the attack of a species of *Phoma*. Inoculation experiments showed that the disease was readily communicated, shoots which were inoculated generally dying in from 4 to 10 days. The species of the fungus has not yet been determined, and from the nature of the attack it is thought that the disease could probably be controlled by spraying with Bordeaux mixture, as suggested for the anthracnose.

Report of the department of botany, A. A. TYLER (*Arizona Sta. Rpt.* 1900, pp. 167-170).—A brief account is given of the investigations which have been conducted at the station on the crown gall, the detailed report on which is given in Bulletin 33 (E. S. R., 12, p. 458). Experiments have been continued on alfalfa root rot, in which plats have been laid off, divided into equal portions, and treated with

a number of fungicides, such as copperas, Bordeaux mixture, ammoniacal copper carbonate, corrosive sublimate, sodium carbonate, and creolin. The effect of digging trenches around infested areas has also been the subject of examination, and the resistance of different varieties of alfalfa is being studied. A report on these studies is to be expected in the future. Notes are given on the collection of economic cacti at the station, and attention is called to the prevalence of the sorghum smut in different parts of the Territory. For the prevention of this disease, the author recommends the Jensen hot-water treatment.

The rust of flax, L. MARMIER (*Misc. Biol. ded. au A. Giard, Paris, 1899, p. 440; abs. in Centbl. Bakt. u. Par., 2. Abt., 6 (1900), No. 17, p. 568*).—The so-called rust of flax is said to be due to an anaerobic bacillus. The pectose of the cell membrane is said to be changed to calcium pectate under the influence of the organism.

Wheat diseases, R. HELMS (*Jour. Dept., Agr. West. Australia, 1900, Feb., pp. 22-32, figs. 3*).

Some experiments in dealing with bunt, or the stinking smut of wheat, W. FARRER (*Agr. Gaz. New South Wales, 11 (1900), No. 5, pp. 335-344*).

Diseases of the sugar cane (*Prog. Mexico, 7 (1900), No. 321, pp. 517-520*).

A turnip disease, W. CARRUTHERS (*Jour. Hort., 52 (1900), No. 2711, p. 244*).—A brief note is given on a disease of turnips and swedes that is due to bacteria.

The rusts of horticultural plants, B. D. HALSTED (*Trans. Massachusetts Hort. Soc. 1900, I, pp. 11-29, pls. 2*).—A lecture in which a number of common rusts are described and preventive treatments recommended.

Diseases of celery, H. H. HUME (*Florida Sta. Rpt. 1899 and 1900, pp. 34-37, pls. 2*).—A popular description is given of the celery blight (*Cercospora apii*), center blight which is probably of bacterial origin, and the leaf spot (*Septoria petroselinii apii*), together with remedies suggested for their repression.

Fungus diseases of cucumbers, tomatoes, and lettuce under glass, G. E. STONE (*Trans. Massachusetts Hort. Soc., 1900, I, pp. 117-126*).—A lecture in which the diseases of these plants when grown under glass are described.

Downy mildew of the cucumber, H. H. HUME (*Florida Sta. Rpt. 1899 and 1900, pp. 30-34, pl. 1*).—The downy mildew of the cucumber (*Plasmopara cubensis*) is described and its occurrence in the United States is historically reviewed. The characteristics of the disease are shown, and it is stated that in Florida the fungus lives and thrives throughout the entire year, so that the formation of resting spores is not essential. A brief account is given of experiments conducted for the repression of this disease, in which the plants were sprayed with Bordeaux mixture. Rainy weather followed the application of the fungicide, the rainfall being so heavy as to destroy many of the plants, but upon those surviving the effect of the spraying was quite marked.

Yellows in peach trees (*Gard. Illus., 22 (1900), No. 1138, p. 573*).—Suggestions are given as to increasing the vigor of trees so as to prevent peach yellows.

Wart-like outgrowths on *Pirus malus chinensis*, N. W. KISSA (*Ztschr. Pflanzenkrank., 10 (1900), No. 3-4, pp. 129-132, pls. 2*).—The occurrence of peculiar outgrowths is mentioned and their anatomical structure described. They are believed to be of little injury to the plants bearing them, aside from the material required for their formation and their disfiguring the host. They are rather small and have somewhat the appearance of clusters of buds.

The treatment of the fumagine of grapes, L. DEGRULLY (*Prog. Agr. et Vit. (Éd. L'Est), 22 (1901), No. 3, p. 67*).—Notes are given on this disease, and the treatment previously recommended (E. S. R., 12, p. 61) is again advised.

A disease of grapes in the Caucasus, L. MONTEMARTINI and L. FARNETI (*Extr. Atti R. Inst. Bot. Univ. Pavia, n. ser., 7 (1900), pp. 14, pl. 1*).—*Physalospora voronini*, n. sp., is described.

The biology and practical prevention of the leaf rust of white pine, C. VON TUBEUF (*Abr. K. Gesundheitsamte, Biol. Abt., Leaflet 5, pp. 4, figs. 3*).

A new parasite of Caragana, A. DE JACZEWSKI (*Rev. Mycol.*, 22 (1900), No. 87, pp. 79-82, pl. 1).—A description is given of *Pleospora caraganæ*, n. sp., found parasitic on the leaves of *Caragana arborescens* in Russia. A list of other fungi occurring on the leaves, branches, and trunk of this tree is given.

A new disease of Solomon's seal, A. DE JACZEWSKI (*Rev. Mycol.*, 22 (1900), No. 87, pp. 78, 79).—The author describes *Cylindrosporium komarovi*, n. sp., as parasitic on the leaves of *Polygonatum humilis*.

A new species of Exobasidium, BOUDIER (*Bul. Soc. Mycol. France*, 16 (1900), No. 4, pp. 15-17, pl. 1).—A description is given of *Exobasidium brevieri*, n. sp., parasitic on *Asplenium filix-femina*. It is closely related to *E. graminicolum*, a common parasite on the leaves of various grasses.

Parasitic algæ and fungi of Java, M. RACIBORSKI (*II and III*, pp. 46 and 49; *abs. in Bot. Centbl.*, 84 (1900), No. 10, pp. 316-319).—About 110 species are described, of which 88 are new species and 11 new genera.

Notes on the temporary injury due to copper fungicides (*Ztschr. Pflanzenkrank.*, 10 (1900), No. 5, pp. 311, 312).—The leaves of a number of varieties of apple trees are said to have been temporarily injured by spraying with Bordeaux mixture.

Concerning copper soda and the use of greater or less amounts of copper sulphate in combating leaf diseases, J. NESSLER (*Wchnbl. Landw. Ver. Baden*, 1900, No. 11, pp. 145, 146).

ENTOMOLOGY.

Report of the entomologist, H. A. GOSSARD (*Florida Sta. Rpt.* 1899 and 1900, pp. 53-75, pl. 1, figs. 5).—The West India peach scale (*Diaspis amygdali*) is reported as having been unusually injurious during the past season. A brief account is given of its distribution according to the present knowledge of the subject, and the use of mechanical mixtures of kerosene and water are recommended in combating it.

The San José scale has been found in 13 counties of the State. This insect was attacked by a fungus disease, *Sphaerostilbe coccophila*. This fungus has been sent to other States by special request. During the year experiments were made with crude oil and kerosene in combating the San José scale upon peach, pear, and plum trees. On the 25th of January undiluted crude petroleum was applied with an emulsion nozzle to pear trees which were badly infested. All scales were apparently killed, but a part of the trees subsequently died of fire blight, so that it was impossible to determine what the effect of the petroleum was upon the trees. A number of plum trees were sprayed on the same day with undiluted petroleum. A greater number of the sprayed trees died than of those in the check row and were more injuriously affected than trees in adjoining rows that were sprayed with a 30 per cent mechanical mixture of crude oil and water. Experiments with undiluted crude oil on peach trees indicated that it is unsafe in Florida to apply this remedy to peach trees. The author concludes that great care should be exercised in the use of undiluted crude oil, and recommends that it should preferably be diluted before using.

The white fly (*Aleurodes citri*) was unusually injurious during the past year. The author recommended the use of resin wash to the fruit growers and received favorable reports concerning its effectiveness.

A number of experiments in fumigating with hydrocyanic-acid gas indicated that the white fly, red spider, and other insects were successfully killed by this method, but the author believes that the heavy dews of Florida will render the fumigation method more difficult than in California.

The cottony cushion scale is reported as having been preyed upon extensively by the caterpillar of *Latilia coccidivora*. The scale was nearly exterminated by the agency of this caterpillar in some localities. A fungus disease was observed to cause the destruction of about 95 per cent of the scales in a few localities. The fungus parasite has not been studied and its relationship is not understood.

Attempts which were made in colonizing the Australian lady bug were without marked success. Brief notes are also presented on a number of scale insects and upon the pickle worm, melon borer, cucumber beetle, bollworm, and other injurious insects.

Report of the Illinois State entomologist concerning operations under the horticultural inspection act, S. A. FORBES (*Springfield, Illinois: Phillips Bros., 1900, pp. 30*).—The duties of the entomologist as prescribed under the horticultural inspection act fall under the two heads of nursery inspection and insecticide treatment of orchards and other property. During the first annual inspection the State was divided into 4 districts and an inspector was assigned to each district. The total number of premises inspected during the first year was 275. In only one case was a certificate refused to the owner of a nursery, and this was on account of San José scale being found on the trees left over from the sales of preceding years. The salaries and expenses of inspectors are charged against the nurserymen who receive their services. The average charge for the first year's work was \$5.77, and for the second year's work, \$3.74.

The woolly aphis was found in considerable numbers in 61 of the nurseries which were inspected. Brief notes are given on the root rot of apple and on the peach-tree borer. The disease known as crown gall was found in 52 nurseries. San José scale has been detected in 6 nurseries within the limits of the State, but has subsequently been exterminated in all except one. The number of localities in the State at which San José scale has been found amounts to 44, but the scale was subsequently exterminated in 10 of these places. In the majority of cases specimens which were sent in under the suspicion of being the San José scale proved to be the scurfy scale. Insecticide treatments against the San José scale include spraying with whale-oil soap, 2 lbs. to the gallon of water, kerosene in a mechanical mixture with water, and fumigation with hydrocyanic-acid gas. The kerosene emulsion was diluted so as to contain 17 per cent of the oil. The general

results of insecticide treatment discourage any hope of exterminating the scale by a single application. Brief notes are also added on the cankerworm and peach yellows.

As the result of the horticultural law, an annual inspection of nursery stock has been carried out, from which a rapid improvement in the condition of Illinois nurseries is evident. The San José scale has been detected in 6 nurseries and has been apparently exterminated in 5 of these. The annual inspection of orchards has resulted in the early discovery of the San José scale in many localities and the prevention of its distribution to a large extent. The author believes that the general operations of the law are beneficial.

Report of injurious insects and common farm pests during the year 1899, with methods of prevention and remedy, E. A. ORMEROD (London: Simpkin, Marshall, Hamilton, Kent & Co., 1900, pp. 152, figs. 28).—The cabbage butterflies (*Pieris brassicae*, *P. rapæ*, and *P. napi*) are discussed, brief notes being given for distinguishing the 3 species. An experiment was tried in dusting cabbages with a mixture of lime and soot. This application seemed to be useless. Another experiment was tried in spraying cabbage plants with Little's Antipest. This remedy seemed to be effective, and it is stated by the author that it may be used as a substitute for kerosene emulsion. A report is made by W. Bailey on the result of allowing two small boys to catch cabbage butterflies with nets during the noon hour for 7 days. They captured 834 butterflies, and it was noted that this had a striking effect in diminishing the number of caterpillars.

The habits, life history, and remedies to be used against *Piophilæ casei* are given, and detailed reports presented from a number of persons who suffered loss from the attacks of this insect upon ham, bacon, or cheese. As remedies, the author recommends the careful screening of all doors and windows, thorough fumigation in early spring or whitewashing with an addition of carbolic acid, careful cleaning of shelves and the use of live steam where possible for disinfecting such places, inclosing cheese in calico caps to prevent the attacks of the flies, the use of strong bags about ham and bacon, and cutting out portions of cheese and ham that are found to be already infested by the insect.

Clover weevils are discussed, the following species receiving consideration: *Apion apricans*, *A. assimile*, and *A. trifolii*. A detailed description of the larvæ and pupæ of *A. apricans* is given. As remedies against this insect, the author suggests early cutting or feeding of the crop before the heads of clover are in condition to give shelter to the weevils for egg laying. In cases of unusually serious outbreaks of this insect, spraying with Paris green or kerosene emulsion is recommended.

Notes are given on certain insects affecting grasses and cereals. Three species of crane flies (*Tipula oleracea*, *T. maculosa*, and *Pachyrhina maculosa*) are mentioned as especially injurious to meadows and pastures. Applications of guano alone, or mixed with salt, kainit, and superphosphate, have been found to assist the infested plants to outgrow the attacks of these insects. Applications to the soil of nitrate of soda and gas lime are also recommended. Salt applied alone failed to be of service in many cases, but as a preventive dressing before plowing was found to be of value.

Notes are given on the habits and life history of the Hessian fly, together with an account of its destructiveness in various parts of England. For the purpose of preventing injuries from this insect, the author recommends sowing wheat after danger of infestation from the Hessian fly is past, and the burning of infested chaff and screenings.

The enemies of the currant received consideration. *Phytoptus ribis* was carefully studied with reference to determining the means of distribution of this insect. A number of experiments conducted by the author and her correspondents indicate that the soil about the roots of infested plants does not contain the mite. The exact manner in which this mite extends its distribution is not known. The only practicable remedy suggested is the breaking off and destruction of infested buds. *Cidaria dotata* is described and figured, with a brief account of its injurious attacks upon red currants. As remedies against this insect, the author recommends the collection of the web cocoons by hand-picking, and their destruction.

Notes are given on certain flour and grain beetles, including the following species: *Tribolium ferrugineum*, *T. confusum*, and *Tenebrioides mauritanicus*. The remedies to be adopted against the first 2 species include careful cleaning of barrels, bins, or wooden depositories in which infested grain has been kept, heating flour to a temperature of 120 to 150° F., and fumigation with bisulphid of carbon. *Tenebrioides mauritanicus* was introduced into England from Africa, and is known to attack cereals, almonds, nuts, bread, etc. This species was observed to attack *Tribolium ferrugineum*. When the species attacks grain, it is recommended that the bags be disinfected and that the walls receive a thick coating of whitewash.

The grouse fly (*Ornithomyia aricularia*) is described, and notes are given concerning its appearance on other animals besides the grouse. A brief account is given of some of the anatomical structures of this insect.

A discussion is given of the following insects injurious to hops: *Agriotes obscurus*, *A. sputator*, *Athous rhombicus*, and *Psylliodes attenuata*. Notes are presented on the habits and life history of the 3 mentioned species of wireworms, including their occasional carnivorous habits. It had been suggested that rape cake might prove bene-

ficial in the destruction of wireworms, and experiments were tried with this substance with entirely negative results. Experiments were carried on by B. Dyer, during which 100 wireworms were placed in each of 3 jars of earth and fed, respectively, with castor-oil seed cake, rape cake, and nothing. At the end of 3 months it was found that of the 100 worms which had no food, 98 were alive; of those fed with castor-oil seed cake 93 were alive, and of those fed upon rape cake only 6 were alive. In the jar of earth which contained rape cake, uncongenial conditions were brought about by the decomposition of the cake, which was probably largely responsible for the death of the worms. The author gives a brief account of the life history and habits of *Psylliodes attenuata*. As remedies against this insect, the destruction of rubbish and old vines and applications of various substances to the soil about the roots of hops are recommended. The substances mentioned for this purpose include kainit, a mixture of kerosene and sawdust, gas lime, lime wash and Paris green, and Bordeaux mixture.

The author gives a detailed account of the life history, habits, and remedies to be used against *Ephestia kuehniella*. Whitewashing infested mills with fresh slaked lime and oil and fumigation were found to be effective remedies. According to the author's observations, the insect does not attack grain in Great Britain. Besides the remedies already suggested, all suspected material should be quarantined in a warm place for a sufficient length of time to allow the infestation, if present, to show itself. An experiment was tried in one mill of stopping work for a week, cleaning all machines, and treating the walls and floor of the mill with live steam and also with fresh slaked lime and kerosene. The results of this experiment were encouraging, although the pest was not entirely exterminated.

Insects injurious to the pear are discussed. The pear gnat midge (*Diplosis pyricora*) is described and notes are given on the various points of its life history which are of economic importance. Experiments in preventive and remedial measures against this insect indicate that good results may be expected from gathering and destroying infested fruits and by removing and burying a thin layer of the soil from near the base of infested trees. Good results were also obtained by the application of kainit to soil around trees and from a similar use of muriate of potash. *Selandria atra* is reported as injurious to the pear and cherry. Notes are given on its egg laying and other habits. Experiments in combating this insect indicate that it is present in all stages in August, and that the application of kerosene emulsion is ineffective, as was also an application of hot lime. Paris green applied as a spray gave fairly good results. The author recommends the removal of the surface layer of infested ground to the depth at which the cocoons lie.

A land planarian (*Bipalium kewense*) is reported as having frequently been found in greenhouses and other situations, where it was suspected of being injurious. This group of flatworms, however, is not known to be injurious to plant life. This species is known to have lived in the Kew greenhouses for a period of about 8 years.

Dicranura vinula has attracted attention as being injurious to poplars and willows. Where the attacks of this insect become serious, the author recommends handpicking of the larvæ.

Notes are given on the habits and life history of *Lampronia rubiella*. Perhaps the most effective method of checking the attack of this insect consists in breaking off and destroying the infested buds of raspberries.

A species of slug (*Testacella haliotidea*) is described and notes are given on its habits. This species was observed eating earthworms, and is, therefore, considered to be a beneficial species in greenhouses.

The mottled willow weevil (*Cryptorhynchus lapathi*) has long been known to be injurious to willows and alders in England. Where signs of infestation by this species are present, the infested branches should be destroyed. When the beetles occur in large numbers on the foliage of these trees, they may be captured by the jarring method.

Brief notes are given on *Timetocera ocellana*, *Cryptococcus fagi*, the winter application of caustic alkali solution for bark beetles of fruit trees *Cephenomyia rufibarbis*, and *Harpalus ruficornis*.

The Angoumois grain moth, J. B. SMITH (*New Jersey Stat. Bul.* 147, pp. 8, figs. 2).—This insect is reported as having been unusually injurious in 1900, causing a loss of about 25 per cent of the entire crop of wheat in the State. The author describes the insect and gives brief notes on its habits and life history. For preventing its ravages, it is suggested that grain be thrashed as soon after harvesting as possible and placed in tight bins or sacks. The grain should be tested occasionally in order to note any heating. If the grain heats decidedly, a serious infestation of the insect may be suspected, and carbon bisulphid should be used at once at the rate of 1 lb. per 250 cu. ft. of space, or 1 dram per cu. ft. It is also recommended that all barns and store-houses should be cleaned, so as to leave no exposed or scattered grain. Such grain may be fed to hogs and chickens.

Report on examination of wheat stubble from different sections of the State; the jointworm in wheat, A. D. HOPKINS (*West Virginia Sta. Bul.* 69, pp. 333-350, pl. 1).—The author examined wheat stubble from 24 counties of the State for the presence of the Hessian fly. He found that nearly all of the flaxseed stage were dead, and more than one-half of them had been killed by parasites. He interpreted these conditions as indicating that the wheat prospects were very encouraging. Tables are given with the names of correspondents, post-office address, dates of sowing, etc., together with the results of the examination of wheat stubble, for the purpose of show-

ing the comparative condition of wheat stubble in different parts of the State.

A brief account is presented of the appearance, life history, and habits of the jointworm. In combating the attacks of this insect, it is recommended that all wheat, barley and rye stubble should be composted or burned before the first of May. The author also recommends cutting grain as high as practicable, and subsequent mowing and collection of the stubble.

The periodical cicada or 17-year locust in West Virginia, A. D. HOPKINS (*West Virginia Sta. Bul.* 68, pp. 257-330, pls. 3, figs. 4).—This bulletin contains a brief account of the anatomy, habits, life history, and broods of the periodical cicada. Notes are given from correspondence relating to the distribution and extent of such broods occurring within the limits of the State. The author states that the cicada probably does not occur in West Virginia above an elevation of 3,300 ft. The time of appearance is influenced to some extent by the average summer temperature, a difference of $3\frac{1}{2}$ days in time of appearance having been noted for each degree of difference in summer temperature. Attention is called to the subsequent attacks of woolly aphids in the wounds caused by the cicadas in depositing their eggs. Tree crickets and certain fungus diseases also find a more easy entrance to trees at such points. The wounds which result from the sting of the cicada may persist for a number of years and cause distortion in the branches of the trees. For preventing serious injury in this way, it is recommended that trees should be severely pruned during the fall after a visitation of cicadas. Especially severe wounds were noted in sugar maple.

Maps are given, showing the distribution of the broods which will emerge in 1901, 1902, and 1905, and warnings are issued for these and other broods. It is recommended that no young fruit trees should be planted in the fall or spring previous to the appearance of the brood of the cicada.

Observations on field slugs and on experiments for the purpose of destroying them, G. DEL GUERCIO (*Nuove Relaz. R. Staz. Ent. Agr.*, 1. ser., 1900, No. 2, pp. 237-267, figs. 2).—The author discusses the literature relating to *Limax agrestis* in connection with a brief bibliographical list. The plants in Italy which are most commonly attacked by this animal are hemp, beans, kidney beans, peas, clover, lucern, wheat, rye, barley, and oats. The injuries caused by the field slug are more or less serious every year, but during certain years the slugs have been so numerous as to cause alarming depredations. The natural conditions which are most favorable for the development of *Limax* are moisture and green vegetation in abundance. Dry areas present a formidable barrier to the distribution of *Limax*.

The natural enemies of the field slug observed in the greatest abundance by the author are *Talpa*, *Gryllotalpa*, *Procrustes coriaceus*, *Silpha laciniata*, and *Lamproyris noctiluca*. A great variety of remedies were tried by the author for the purpose of destroying the field slug. Among the pulverized insecticides, mention should be made of carbonate, oxid, hydroxid, sulphate, and sulphid of calcium, ashes, dust, sulphur, pyrethrum, chrysanthemum, and tobacco. White hydroxid of calcium dusted upon the field slug caused a severe irritation of the skin which resulted in the death of the majority of them. The brown hydroxid of calcium and the oxid of calcium were less efficacious. Ashes proved to be of little value, as nearly all the *Limax* dusted with this substance ultimately escaped. Pyrethrum powder and dusted tobacco were of little avail in combating the field slug. Nearly the same list of substances was tried by way of direct applications on plants for the purpose of preventing the attack of the field slug.

From the numerous insecticide experiments conducted by the author, it is concluded that pulverized white hydroxid of calcium or the same substance in a 1 to 2 per cent solution in water is the most active remedy for the destruction of the field slug. As the second most effective remedy, the author mentions white oxid of calcium. According to his experiments, the most appropriate time for applying artificial remedies in the destruction of *Limax* is from 8 to 9 o'clock in the evening.

Means of protecting barks and woods against insects, E. MER (Bul. Soc. Nat. Agr. France, 60 (1900), No. 11, pp. 673, 674).—It was observed by the author that two years after ringing a number of cork oaks, the region immediately above the ring was badly infested with bark beetles and had been much visited by woodpeckers for the purpose of feeding upon these insects. The region immediately below the ring, however, was entirely free from bark beetles. Since it is known that ringing, if performed so deeply as to injure the cambium, has the effect of causing an accumulation of starchy materials immediately above the cut and the almost complete absence of such materials below the cut, it is suggested by the author to use any means which will hasten the resorption of starch from the bark or which will serve to protect this substance from future insect attacks. Specimens which are intended for museum purposes may be cut in winter or early spring from branches out of which the reserve materials have been removed for winter storage to a lower position.

Spraying, L. C. CORBETT (West Virginia Sta. Bul. 70, pp. 353-382, figs. 17).—A test of the value of spraying was made on an apple orchard 30 years old, with trees standing 33 ft. apart. The trees were regularly sprayed through the season of 1899. In 1900 the orchard was sprayed with Bordeaux mixture and Laurel green, the applications being made on April 19, May 23, June 8, and June 23. The results

indicate that this treatment increases the fruit crop to an extent which warrants the fruit grower in spending the necessary time and money for making the applications. On the Rambo apple trees the yield of fruit was increased 18.3 per cent, and on the Beauty of Kent 62 per cent.

Experiments for checking the attacks of the codling moth show that 12 oz. of Laurel green to the 100 gal. of Bordeaux mixture had little, if any, effect upon the number of the codling moth. A single application of 5 oz. of Paris green to 50 gal. of the Bordeaux mixture reduced the injury from the codling moth to a considerable extent. In this connection, brief notes are also given on the use of arsenate of lead.

Experiments were tried in using a combination of Bordeaux mixture and kerosene, containing 10 to 15 per cent of the latter. The application was made to pears, apples, and plums on April 26 and May 12. No injury to the foliage resulted, and the apple aphid seemed to be entirely destroyed by both the 10 and 15 per cent kerosene combinations.

The author tested the possibility of making Bordeaux mixture by mechanical methods. Two lbs. of copper sulphate were dissolved in 4 gal. of water, and 2 lbs. of lime in 12 gal. of water. The copper sulphate solution was placed in an oil tank and the limewater in the barrel of a Kerowater pump. The pump was set to make a 25 per cent mixture, and thus the lime and copper sulphate were delivered in equal quantities in the nozzle. The only advantage of this method is the lessened liability to clog the pump and nozzle.

A test was made of a combination of tobacco and kerosene emulsion as a remedy for rose bugs. The mixture was made by combining the Riley kerosene emulsion with 2 gal. of tobacco tea. This spray was applied to peach trees without damage to the foliage. Little effect was shown on the rose bugs, since they are of a migratory nature and difficult to combat.

The author gives a brief description of the appearance of the San José scale. Notes are also presented on the spread of this insect in West Virginia. Experiments were tried in combating the San José scale with whale-oil soap, made by dissolving 2 lbs. of soap in a gallon of water, dilute kerosene (150° test), in a 25 per cent mechanical mixture with water, and pure kerosene and crude petroleum in a 20 per cent mixture with water. In preparing these insecticides, it was found that whale-oil soap offered the greatest difficulties. None of the other mixtures require especial preparation. The spraying work was begun on March 28. An inspection of the work on May 16 and on October 12 showed that whale-oil soap had killed a large percentage of the scales and had caused no injury to the trees. Pure kerosene caused no damage to the foliage and killed the scales on the parts of

the trees which had been thoroughly sprayed. A 25 per cent mechanical mixture of kerosene did no damage to the trees, but some live scales were found upon fruit and branches of the trees. The 20 per cent mixture of crude petroleum caused no injury to peach, plum, or apples and killed all scales with which it came in contact. Undiluted crude petroleum was also employed on a small scale on Japanese plum trees with good results and without injury to the tree. Undiluted petroleum was tried in another locality with similar results, the trees having been subsequently found entirely free from living scales. The author states that the undiluted crude petroleum treatment gave the best results of any method which was tried.

The composition of arsenical insecticides, S. AVERY (*Idaho Sta. Bul.* 25, pp. 11).—Analyses were made of 19 samples of Paris green obtained from dealers in different parts of the State. An average of these samples showed copper oxid 30.49 per cent and arsenious acid 56.86 per cent, 3.35 per cent of the latter being soluble. The author estimates that 3 per cent of commercial Paris green may be considered as foreign substances and moisture, which are perhaps unavoidable. The assumption that Paris green is insoluble in water is incorrect, since 55 per cent of the arsenic contents in a pure sample of Paris green was extracted by means of distilled water alone. The author considers the methods of solution in ammonia and passing Paris green over a glass slide to be of some value in determining its quality, but recommends as the only entirely satisfactory test a chemical analysis.

Tests made on the samples of London purple indicated that considerable lime was present in the form of the carbonate. Several samples of Arsenoids were examined by the author, with especial reference to the relative capacity of the bases which they contained to form insoluble compounds with arsenious acid. It was found that the tendency of arsenite of lime to give off soluble arsenic is somewhat reduced by increasing the excess of lime. Brief notes are also added on copper arsenite, barium compounds, lead compounds, and home-made arsenite of lime.

The honeybee, R. HELMS (*Jour. Dept. Agr. West. Australia*, 2 (1900), No. 6, pp. 409-413).—The author calls attention to the great variety of plants in Australia which yield nectar. A considerable number of these plants produce flowers over an extended period. Another advantage for bee keepers in Australia is the mild climate.

The differentiation of cell elements in the ovary of the queen bee, W. PAULCKE (*Zool. Jahrb., Abt. Anat.*, 14 (1900), No. 2, pp. 177-202, pls. 4, fig. 1).—The author gives an account of the generations of cell divisions in the ovaries of queen bees with reference to the proportion and purpose of the nutritive cells and cells which ultimately become eggs. The details of cell differentiation are described for both varieties of cells. A bibliography of the subject is appended.

Drone production, A. GALE (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1095-1098).—The author gives a popular discussion of the relationship of drones to the rest of the colony and to the problem of parthenogenesis in bees.

Do bees damage fruit? J. B. SMITH (*Rural New Yorker*, 59 (1900), No. 2655, p. 830).—The author discusses this subject with especial reference to the evidence presented by Professor Jablowsky of the injury to grapes by bees in Hungary.

The bee moth (*Jour. Jamaica Agr. Soc.*, 5 (1901), No. 1, pp. 16, 17).—Brief notes on the habits and life history of this insect. In combating the bee moth it is suggested that the colonies should be kept in a vigorous condition and that infested colonies should be removed to another hive and the old frames fumigated with sulphur.

Spider or lice flies that infest horses, sheep, and other animals, W. W. FROGGATT (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1088-1094, pl. 1).—The author gives a brief account of the appearance, habits, and life history of *Hippobosca equina*, *H. rufipes*, *H. bactriana*, *H. canina*, *Olfersia macleayi*, and *Melophagus ovinus*. Mr. E. Stanley reports the case of a pony which became uncontrollable under the irritating attacks of *H. equina*.

The more common insect pests of the farm and market garden, A. M. LEA (*Jour. Dept. Agr. West. Australia*, 2 (1900), No. 6, pp. 399-408, figs. 8).—This article contains brief notes on the chinch bug, Hessian fly, Australian chinch bug (*Nysius vinitor*), Australian plague locust (*Pachytilus australis*), the bollworm, *Anoplostethus opalinus*, and species of thrips and mites, including red spider and other species.

The enemies of cereals, V. MAYET (*Prog. Agr. et Vit. (Éd. L'Est)*, 21 (1900), No. 52, pp. 790-794).—The author gives an account of the habits and life history of *Cephus pygmaeus*. This species is attacked by a hymenopterous parasite, *Pachymerus calcitrator*. The wheat nematode *Tylenchus tritici* is reported as exceedingly injurious in certain localities. A detailed description is given of the worm. In order to destroy the nematodes in seed wheat the author recommends soaking the wheat for 24 hours in a solution of 1 part sulphuric acid in 150 parts of water.

Entomologist's report, A. KOEBELE (*Hawaiian [Sugar Planters'] Sta. Rpt.* 1900, pp. 40-42).—Brief notes are given on insects which were found on dead and dying sugar cane. Ants were found in considerable numbers, but were probably attending the mealy bug, *Dactylopius calceolariae*. Nematode worms were found in dying roots, but were probably not injurious to living sugar cane.

Notes on insect pests from the entomological section (*Indian Mus. Notes*, 5 (1900), No. 2, pp. 39-54).—The chief insect enemies of sugar cane during the year were *Chilo simplex*, *Ripersia sacchari*, *Dictyophora pallida*, and *Termes taprobanes*. *Hispa anescens* is reported as very destructive to cereal crops, especially in paddy fields. Experiments were tried in dusting the plants with sulphur, smoking with sulphur, and spraying with copper sulphate solution 1 part to 100 and 1 part to 200 of water, and with carbolic acid solution 1 part to 20 parts of water. The insects dropped off the leaves as soon as the last-mentioned insecticide touched them, but seemed later to recover. The bollworm was reported as damaging paddy seedlings and cotton in several localities. Brief notes are given on insect pests of maize, wheat, tea, cocoanut palm, and forest trees.

The Hessian fly, A. E. JENKS (*Amer. Thresherman*, 3 (1901), No. 9, pp. 42, 43, figs. 2).—The author discusses briefly the history of the Hessian fly, its present distribution in the United States, the means for its dispersal, the appearance of the insect in its different stages, its food plants, natural enemies, and the most effective remedies which have been recommended against it.

Description of a new species of *Ripersia* destructive to sugar cane, E. E. GREEN (*Indian Mus. Notes*, 5 (1900), No. 2, pp. 37, 38, figs. 2).—*R. sacchari* is described as a new species, and reported as occurring on the leaves of sugar cane. The insect has a more or less globular form, and in appearance seems to be most closely related to *R. pulvinaria*, which appears on grasses.

The cane shot borer (*Xyleborus perforans*), L. ZEHNTNER (*Meded. Proefstat. Suikerriet. West Java*, 1900, No. 44, pp. 21, pl. 1, dgm. 1).—The author gives a detailed account of the habits of this insect, which usually attacks sugar cane at the nodes.

A discussion is also given of the injury caused by the beetle. The insect is described in detail in its various stages.

The author believes that there is no urgent demand for insecticide methods against this insect, since apparently its attacks are for the most part confined to sugar cane which is already infested with some fungus disease. The prompt removal and destruction of canes which are infested with any fungus disease is suggested as a good means for preventing further injury by the shot borer.

The fruit fly, A. H. BENSON (*Queensland Agr. Jour.*, 7 (1900), No. 6, p. 524).—For the destruction of this insect the author recommends that all infested fruit should be boiled. It is considered especially important to destroy the early brood of larvæ.

The Dermaptera and Orthoptera of Austro-Hungary and Germany, J. REDTENBACHER (*Die Dermapteren und Orthopteren von Österreich-Ungarn und Deutschland*. Vienna: Carl Gerold's Son, 1900, pp. 148, pl. 1).—The author discusses briefly the general anatomy, different methods of capture and study of these groups of insects. A systematic account is presented of the different species which occur within the limits indicated. A bibliography of the subject is appended.

Illustrated analytical fauna of the Orthoptera of France, C. HOULBERT (*Faune analytique illustrée des Orthoptères de France*. Paris: Emile Deyrolle's Sons, 1900, pp. 55, figs. 218).—The author gives analytical tables by which the species of Orthoptera which occur in France may be determined. The majority of the species are illustrated. The anatomy of this group of insects is briefly discussed, and a bibliography of related literature is given.

The natural history of the British Lepidoptera, J. W. TUTT (*London: Swan Sonnenschein & Co., 1899, Vol. I, pp. 560*).—The present volume is divided into 2 parts, of which the first contains a general discussion of the origin of Lepidoptera, the egg, embryology, parthenogenesis, external and internal structure of caterpillars, variation of moths, protective coloration, and a system of classification of Lepidoptera. The second part of the volume begins a detailed discussion of the families of this order. The practical value of this volume is considerably increased by full bibliographical references.

The critical point in insects and the origin of butterfly aberrations, P. BACHMETJEV (*Illus. Ztschr. Ent.*, 5 (1900), No. 6, pp. 86-89).—If adult or larval insects are kept at a temperature of -25° C. their body temperature is gradually diminished, and during this time certain peculiar developments are observed. At about -10° C. the body temperature of the insects is suddenly elevated up to -1.5° C. or to 0° C. The elevation of temperature is explained by supposing that latent heat is set free by the process of passing into the so-called cold rigor. The observations of the author were carried out upon a considerable variety of insects.

On certain seasonal phases of butterflies of the genus *Precis*, A. G. BUTLER (*Entomologist*, 34 (1901), No. 452, p. 7).—A brief discussion of the various forms of the species belonging to this genus.

Description of a new species of *Aleurodes* destructive to betel, G. B. BUCKTON (*Indian Mus. Notes*, 5 (1900), No. 2, p. 36, figs. 3).—A species described under the name *A. nubilans* is reported as occurring in large numbers on the under side of betel leaves in the form of small scales, difficult to detach. The larvæ were tufted with yellow material, each thread forming a continuous spiracle.

On the occurrence of *Colias edusa* and *C. hyala*, and the results of rearing the variety *helice* from *helice ova*, F. W. FROHAWK (*Entomologist*, 34 (1901), No. 452, pp. 2-5).—The results obtained from experiments with the variety *helice* indicated that this form was almost as numerous as the normal females, the same number of each having emerged for several days.

The claws and pulvilli of Diptera, J. J. KIEFFER (*Illus. Ztschr. Ent.*, 5 (1900), No. 22, pp. 339, 340, pl. 1).—A brief anatomical study of the structures.

Notes on the life history of *Anopheles maculipennis*, L. W. SAMBON (*British Med. Jour.*, 1901, No. 2091, *Epid.*, pp. 195-199, pl. 1, figs. 8).—The author describes

from the literature of the subject and from personal observations, the various details of structure, life history, and habits of this species in all its stages. Especial attention is given to a discussion of the breeding grounds of these mosquitoes.

New guests of the Dorylinæ of the Neotropic and Ethiopian regions, E. WASMANN (*Zool. Jahrb., Abt. Syst.*, 14 (1900), No. 3, pp. 215-289, pls. 2).—This paper contains a discussion of the robbing habits of these ants, together with brief notes on their so-called "guests," and descriptions of new species.

The larva of Lonchoptera, J. C. H. DE MEIJERE (*Zool. Jahrb., Abt. Syst.*, 14 (1900), No. 2, pp. 87-132, pls. 3).—An elaborate account of the anatomical structure and physiological relations of this genus.

A report on the injurious outbreaks of *Lymantria monacha* in Södermanland and Östergötland in the year 1899, together with measures for combating this insect, J. H. WERMELIN ET AL. (*Ent. Tidskr.*, 21 (1900) No. 2, pp. 97-111).—An apparently infectious disease of the larvæ of this species was noted and tables were given showing the number of diseased and parasitized larvæ among a large number of specimens which were collected. Brief notes are given on the insect enemies of the insect in its various stages. In combating the attacks of this insect Raupenleim and banding methods were used.

Description of a new species of *Psylla*, destructive to forest trees, G. B. BUCKTON (*Indian Mus. Notes*, 5 (1900), No. 2, pp. 35, 36, figs. 6).—A technical description is given of a new species under the name of *P. obsoleta*. The insect was reported as injurious to young specimens of *Diospyros melanoxylon*. The leaves of the young plant were attacked and galls were formed. The insect left its gall in January or February. After the departure of the insect the galls disappeared, leaving small holes in the leaves.

A hemipterous insect parasite upon *Hyponomeuta malinellus* and *H. padeilus*, A. GIARD (*Bul. Soc. Ent. France*, 1900, No. 18, pp. 359, 360).—The larvæ of these insects are reported as being parasitic to a considerable extent upon *Atractotomus mali*.

FOODS—ANIMAL PRODUCTION.

The availability and fuel value of food materials, W. O. ATWATER and A. P. BRYANT (*Connecticut Storrs Sta. Rpt.* 1899, pp. 73-110).—The authors discuss the so-called availability of foods (see p. 1075), the proportion of nutrients supplied by different groups of food materials in the average diet, the availability of different classes of nutrients in food of mixed diet, heats of combustion of nutrients, fuel value, and related topics. The discussion is based upon the results of nutrition investigations carried on under the auspices of the Department of Agriculture as well as those carried on at the station. A large number of analyses have shown that the ordinary factor for computing protein, *i. e.*, 6.25, is not applicable to all classes of food. The following factors are proposed:

Proposed nitrogen factors for the protein of different groups of food materials.

Kind of food material.	Factors proposed.	Factors for re-calculating protein.
Animal foods	6.25	
Wheat, rye, barley, and their manufactured products.....	5.70	0.912
Maize, oats, buckwheat, and rice, and their manufactured products.....	6.00	.960
Dried seeds of legumes.....	6.25	
Vegetables	5.65	.904
Fruits	5.80	.925

As regards heat of combustion and fuel value, the following statements are made:

"Taking into account (1) the heats of combustion of the protein compounds, fats, and carbohydrates which occur in different groups of food materials, and (2) the average proportion in which the different nutrients are furnished by different food materials in the ordinary mixed diet, the average heat of combustion of 1 gm. of protein, fat, and carbohydrates in such diet is approximately 5.65, 9.40, and 4.10 calories, respectively.

"One gram of total protein of mixed diet burned in the body yields on the average not far from 4 calories, 1 gm. of fat 8.9 calories, and 1 gm. of carbohydrates 4 calories of energy. The corresponding values per pound are 1,820, 4,240, and 1,820 calories. One gram of available protein, on the other hand, has a fuel value of 4.4 calories, 1 gm. of available fats 9.4 calories, and 1 gm. of available carbohydrates 4.1 calories. These values correspond to 2,000, 4,260, and 1,860 calories per pound.

"Of course these figures are not to be regarded as final, and alterations may be called for as data accumulate. Meanwhile we think that they are sufficiently accurate for ordinary use."

The relative proportion of total food and total nutrients supplied by a number of food materials and groups of foods, as shown by the results of 185 dietary studies, follow:

Relative proportions of total food and of total nutrients supplied by different groups of food materials in average of 185 dietary studies.

Kind of food material.	Total food.	Protein.	Fat.	Carbohy- drates.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
Beef and veal.....	10.3	24.6	19.5
Mutton and lamb.....	1.4	3.3	3.8
Pork.....	5.4	8.8	30.0
Poultry.....	1.1	2.6	1.2
Fish, shellfish, etc.....	1.9	3.7	.8	0.1
Total meat, etc.....	20.1	43.0	55.3	.1
Eggs.....	3.0	5.9	4.3
Butter.....	1.9	.2	19.7
Cheese.....	.4	1.6	1.6
Milk and cream.....	19.9	10.5	10.7	5.3
Total dairy products.....	22.2	12.3	32.0	5.3
Total animal food.....	45.3	61.2	91.6	5.4
Corn meal, rye, and buckwheat flour.....	1.8	1.9	.4	5.2
Oatmeal, rice, and wheat preparations.....	1.3	2.1	.6	3.6
Wheat flour, bread, crackers, pastry, etc.....	18.7	26.5	6.0	45.9
Total cereal products.....	21.8	30.5	7.0	54.7
Starch.....	.12
Sugar.....	5.5	21.0
Dried legumes.....	.6	2.0	.1	1.3
Potatoes and sweet potatoes.....	13.7	3.9	.3	10.0
Other vegetables.....	7.4	1.8	.4	2.5
Total vegetables.....	21.1	5.7	.7	12.5
Fruits.....	5.6	.6	.6	4.9
Total vegetable food.....	54.7	38.8	8.4	94.6
Total food.....	100.0	100.0	100.0	100.0

The average coefficients of availability of the nutrients of different groups of food materials and of the total nutrients of a mixed diet are given.

"The results of a considerable number of digestion experiments with mixed diet give averages for coefficients of availability as follows: For protein, 92 per cent; fats, 95 per cent, and carbohydrates 97 per cent."

Studies of dietaries of college students and of members of families of professional men, W. O. ATWATER and R. D. MILNER (*Connecticut Storrs Sta. Rpt. 1899, pp. 124-149*).—Details are reported of a dietary study with college students, a chemist's family, and a chemist. The students and the chemist were young men in good health. The subject of one of the studies, No. 316, boarded himself during a summer vacation. Most of the foods eaten were such as could be purchased already prepared or canned. A very considerable number were of vegetable origin. In the dietary study of the chemist's family, No. 317, the special object was to determine whether salt cod-fish and dried beans prepared in different ways could be used with satisfaction as sources of protein in place of a considerable portion of the meat ordinarily used. The results of the dietary studies follow:

Average results of dietary studies; quantities consumed per man per day.

	Cost.	Protein.	Fat.	Carbo- hydrates.	Fuel value.
	<i>Cents.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Grams.</i>	<i>Calories.</i>

Investigations on the metabolism of matter and energy of full-grown steers on a maintenance and on a productive ration, O. KELLNER, A. KÖHLER, ET AL. (*Landw. Vers. Stat., 53 (1900), pp. X+474*). Continuing the experiments with steers on the metabolism of matter and energy at the Möckern Experiment Station (E. S. R., 10, p. 669), the authors report in detail a considerable number of investigations. These include four series, aggregating 39 individual experiments of an average duration of 14 days. A total of 159 respiration experiments were made, each of 24 hours' duration, with the Pettenkofer respiration apparatus. In the first series the ration consisted of gluten and starch; in the second, of gluten, starch, and oil; in the third, of meadow hay, oat straw, starch, oil, and molasses; and in the fourth, of meadow hay, oat straw, starch, extracted rye straw, and molasses. The composition and digestibility of the ration was studied; record was made of the water consumed and its content of carbon dioxide; the urine was analyzed; the carbon in the gaseous excretory products, the nitrogen, and carbon balance were determined, as well as the fuel

value of the income and outgo. From the observed data the gains in fat and muscular tissues were calculated, as was also the energy balance. Detailed records were kept of the temperature of the stalls, and all the experimental data of the metabolism, digestion, and respiration experiments are recorded in detail, the experimental data being followed by a general discussion of results and statements of some of the principal conclusions and deductions. A number of these conclusions and deductions follow:

On an average it was found that the steers consumed 1 kg. of water per 3.3 kg. of dry matter in the food. Of the water consumed as such and in the food, 46.3 per cent was excreted in the feces and 29.2 per cent in the urine.

The investigations of the fuel value of the food and excretory products indicate that within wide limits it is possible to calculate the true energy value of the digested food with a reasonable degree of accuracy. In the experiments reported the fuel value per gram of digestible material was calculated for a number of feeding stuffs when added to a maintenance ration. The values obtained were the following: Starch, 4,185 calories; gluten protein, 6,148; peanut oil, 8,821; molasses, 4,075; "straw-like material," i. e., crude fiber and nitrogen-free extract, 4,247; meadow hay, 4,437; oat straw, 4,513, and wheat straw, 4,470 calories.

In the different experiments determinations were made of the amount of methan excreted, and the proportion of methan carbon to total digestible carbon and to carbon of nitrogen-free extract and crude fiber was calculated. On an average it was found that there was produced per 100 parts of digestible carbohydrates 3.14 parts of methan carbon=4.2 parts of methan. According to the authors, the digestible protein present in the ration had no direct effect on the formation of methan. Fat and oil in the finely divided form in which they were consumed in the ration did not produce methan fermentation. Oil consumed as such in large quantities hindered this fermentation.

The fuel value of the urine was determined under the different food conditions of the several experiments. In effect, the authors state that the determinations made in the 44 experimental periods indicate that within certain bounds, as regards protein consumed, the carbon content of the urine furnishes a very nearly accurate measure of the fuel value of the total dry matter of the urine.

The "physiological-nutritive value" of the different feeding stuffs is discussed. By this term the authors mean the amount of energy which remains for the use of the body after the energy necessary for the labor of chewing and digestion, or formation of urea, is deducted. The physiological nutritive value per gram of the different feeding stuffs tested, when forming a part of a ration for maintenance and when

constituting that portion of the ration which serves for production, is shown in the following table:

Physiological nutritive value of different feeding stuffs.

Feeding stuffs.	In ration for maintenance.	In amount available for production.	
	<i>Calories.</i>	<i>Per cent.</i>	<i>Calories.</i>
Gluten protein	4,958	45.2	2,241
Peanut oil.....	8,821	56.3	4,966
Starch	3,760	58.9	2,215
"Straw-like material"	3,651	63.1	2,304
Molasses No. 1.....	3,829	58.9	2,255
Molasses No. 2.....	3,462	68.3	2,365
Meadow hay No. 5.....	3,553	40.2	1,428
Meadow hay No. 6.....	3,728	42.8	1,596
Oat straw.....	3,747	37.6	1,409
Wheat straw.....	3,327	17.8	592

The authors calculate that fat is formed from starch according to the following equation: 100 gm. starch + 38.69 gm. oxygen = 3.17 gm. methan + 23.4 gm. water + 88.77 gm. carbon dioxid + 23.34 gm. fat. The results of the tests are believed to show further that protein is to be regarded as a source of fat. The digestible crude fiber in the straw freed from encrusting material is stated to possess a nutritive value not at all inferior to that of digestible starch. The furfural-yielding substances of a ration are regarded as not inferior to starch or cellulose for the formation of fat. The easily digestible cellulose of extracted rye straw, in the authors' opinion, protected protein and rendered it available for the formation of muscular tissue.

The following are enumerated as the causes of the loss of energy when organic substances are digested, absorbed, and converted into body tissue: (1) The labor of chewing and digesting, including that required for the absorption of water to moisten the food for solution and the action of enzymes in the feeding stuffs; (2) the formation of methan by fermentation which, as shown by the authors' observations, is limited to the nitrogen-free material and crude fiber and does not concern the protein and fat; (3) destruction of food by the large number of micro-organisms in the intestinal tract, further aided by the length of time the material remains in the intestinal tract of ruminants; (4) the incompletely oxidized material which is excreted in the urine; and (5) the molecular rearrangement of absorbed material when it is converted into body substance, a change which probably requires a considerable energy expenditure.

Further, the productive value of feeding stuffs depends not alone, according to the authors, upon its content of digestible nutrients, but is materially affected by the physical properties of cell tissue and the presence of undigestible so-called encrusting substances. All such conditions which increase the labor of chewing and digesting or the solution and absorption of the nutrients enclosed in cells, diminish the

productive value of a feeding stuff. Whether the food is rapidly assimilated by the aid of the saliva and juices of the stomach, or whether absorption is brought about in the lower portion of the intestinal tract by decomposition is a matter of great importance.

Feeding steers, G. H. TRUE (*Arizona Sta. Rpt. 1900, pp. 171-174, pl. 1*). According to the author it is a generally accepted fact that while cattle fatten rapidly on alfalfa, they can not be finished for market on this feed alone so as to compare profitably with animals finished on grain. Local feeders have reported favorable results on the use of sorghum fodder as a supplement to alfalfa. The author tested the comparative value of cured corn fodder, Kafir corn fodder, and sorghum fodder as a supplement to alfalfa hay with 2 lots of 4 steers each. During the first 5 weeks of the test lot 1 consumed 1,512 lbs. alfalfa and 1,247 lbs. corn fodder, and made an average daily gain of 1.39 lbs., while lot 2 (fed throughout the test alfalfa hay only) consumed a total of 2,929 lbs. of alfalfa and made an average daily gain of 1.03 lbs. per head daily. When Kafir corn fodder was substituted for corn fodder, in the next 5 weeks of the test, lot 1 ate 1,575 lbs. alfalfa hay and 1,333 lbs. Kafir corn fodder, and gained on an average 1.68 lbs. per head daily. In the same time lot 2 consumed 2,853 lbs. alfalfa hay and gained 1.65 lbs. per head daily. During the following 6 weeks, sorghum fodder was substituted for Kafir corn, and lot 1 consumed 1,890 lbs. alfalfa hay and 1,814 lbs. of sorghum, and gained 1.65 lbs. per head daily. Lot 2 consumed a total of 2,828 lbs. alfalfa and gained 1.67 lbs. per head daily. Considering the test as a whole the gains made by the lot fed alfalfa hay and other forage was 711 lbs. as compared with 652 lbs. on alfalfa hay alone, a difference which the author regards as insufficient for definite conclusions. At the close of the test the lots were rearranged so as to counterbalance the effect of previous rations and each lot was pastured for 8 weeks on 2 acres of alfalfa. Lot 1 was fed sorghum fodder, and lot 2 alfalfa hay in addition. The average daily gain per steer in lot 1 was 1.63 lbs., and in lot 2, 1.55 lbs.

Sheep feeding, G. H. TRUE (*Arizona Sta. Rpt. 1900, pp. 175, 176*). The comparative value of alfalfa hay and of sorghum fodder alone, mixed, and supplemented by sugar beets was tested with 5 lots of 8 sheep each. In 4 weeks lot 1, on a daily ration of 40 lbs. of chopped sugar beets and 20 lbs. of alfalfa, gained on an average 0.259 lb. per head daily. Lot 2, fed 40 lbs. sugar beets and 20 lbs. sorghum fodder daily, made an average daily gain of 0.286 lb. per head. The average daily ration of lot 3 was 40 lbs. alfalfa hay, and lot 4, 40 lbs. of sorghum fodder, and of lot 5, 10 lbs. alfalfa hay and 30 lbs. of sorghum fodder. The average daily gain per head in these 3 lots was 0.187, 0.125, and 0.232 lb., respectively. Although the author believes the test insufficient for general deductions, the fact is pointed out that

there was an undoubted advantage in the use of sugar beets, *i. e.*, succulent food, as part of a ration. At the end of the trial the sheep were not in condition for market and were pastured for 4 months on burr clover or alfalfa, and were fed wheat hay or barley in addition. They were then sold. From the beginning of the test to the end of the pasturage period the average daily gain was 0.32 lb. per day.

On the amount of water in slop fed fattening pigs, C. S. PLUMB and H. E. VAN NORMAN (*Indiana Sta. Bul.* 86, pp. 151-158).—The comparative value of grain fed dry and mixed with different amounts of water was tested with 4 lots of 3 pigs each. For the first 15 weeks of the trial the grain used was corn meal and shorts, 1:1, and for the remaining 6 weeks of the test hominy chop replaced the corn meal. Lot 1 was fed the ration dry; lot 2 received it mixed with an equal amount of water. For lot 3 the grain was mixed with twice, and for lot 4 with three times, its weight of water. In addition to dry grain or slop, the pigs were given all the drinking water they desired, the amounts consumed being recorded. The average daily gain of the 4 lots was $4\frac{1}{3}$, $4\frac{2}{5}$, $4\frac{2}{5}$, and $4\frac{1}{5}$ lbs.; the grain consumed per pound of gain was 3.59, 3.80, 3.74, and 3.75 lbs., while the cost of food per pound of gain was 2.87, 3.04, 2.99, and 3 cts., respectively. Lot 1 drank a considerable amount of water; lot 2 a somewhat smaller amount, while lots 3 and 4 received all they wished in the slop fed. During the test the total amount of water drank by lot 1 was 3,379.5. Lot 2 received a total of 3,031 lbs., while lots 3 and 4 received 4,871.3 and 6,927.9 lbs., respectively.

“Pigs weighing 60 lbs., fed dry feed, consumed on an average 2.35 lbs. daily, and this amount increased nearly constantly until these same pigs, weighing 218 lbs., consumed 11.07 lbs. per day. It is also shown that pigs fed water in their food as a slop, when weighing about 60 lbs., consumed either 2.42, 4.25, or 5.79 lbs. of water per day, while these same pigs weighing 213 to 222 lbs. consumed either 8.17, 14, or 18 lbs. of water per day. Undoubtedly much of this water was consumed unnecessarily, and certainly lot 4 was given much more water with its grain than was required.

“There was no material difference in the appearance of the pigs in either lot, so far as quality is concerned, and so far as this one experiment goes the use of about two times the weight of water to grain indicates a satisfactory proportion. In view of the fact that the pigs fed dry grain made slightly [better gains than the others], it would appear that there is really no gain in feeding the pigs a slop instead of a dry grain, excepting as a feeder may regard it a matter of convenience.”

Discussion of the terms digestibility, availability, and fuel value, W. O. ATWATER (*Connecticut Storrs Sta. Rpt.* 1899, pp. 69-72).—The terms availability, digestibility, and fuel value are discussed at some length and explained. It is proposed to use availability for what is ordinarily termed digestibility—*i. e.*, the total nutrients consumed less the amounts of each excreted in the feces. The author proposes the term digestibility for what is ordinarily called digestibility, with corrections introduced for the metabolic products in the feces. “[By fuel value] is understood the energy (heat of combustion) of the material of the food which is oxidized—*i. e.*,

capable of oxidation in the body. For the total food it is the total energy less that of the corresponding unoxidized materials of the feces and urine. For the protein it is likewise the total heat of combustion less that of the corresponding unoxidized residues of these excretions. For the fats and carbohydrates it is the total energy less the energy of the corresponding unoxidized material of the feces."

Composition of common food materials—available nutrients and fuel value, W. O. ATWATER and A. P. BRYANT (*Connecticut Storrs Sta. Rpt.* 1899, pp. 111–123).—Using the coefficients of availability quoted above (p. 1069) the authors calculated the available nutrients (*i. e.*, what is generally designated as digestibility) in a large number of animal and vegetable foods.

Meat extract and meat peptone, H. BREMER (*Chem. Ztg.*, 24 (1900), No. 79, pp. 838–841).—A general discussion with much historical data.

On the extractive substance of muscular tissue, W. GULEWITSCH and S. AMIRADŽIBI (*Ztschr. Physiol. Chem.*, 30 (1900), No. 6, pp. 565–573).—From meat extract the authors isolated and studied a substance which they consider a new base and to which the name "carnosin" is applied.

Has meat extract nutritive value? L. FÜRST (*Chem. Ztg.*, 24 (1900), No. 91, pp. 994, 995).—A general discussion.

Banana [and breadfruit] flour, W. KIRKLAND (*Jour. Jamaica Agr. Soc.*, 4 (1900), No. 11, pp. 668, 669).—A descriptive article.

Cassava culture in Java; its uses by the natives and for the manufacture of tapioca flour, H. C. DE BIE (*Teysmannia*, 11 (1900), No. 6, pp. 273–298).—Cassava culture in Java is reviewed and a description given of the preparation of tapioca flour. The crude product of native manufacture is further refined, yielding a pure, white flour and a flour of inferior quality. Three parts of the ground rootstock yields 1 pt. of pure tapioca. The material remaining after the manufacture of tapioca is sometimes dried and used for fuel.

The young leaves of certain varieties of cassava are used as pot herbs. The rootstock is eaten boiled or steamed. It is also sliced raw, dried in the sun for 1 or 2 days, and fried in cocoanut oil, being eaten with salt. Alcoholic beverages are made from the rootstock.—H. M. PIETERS.

Starch-yielding plants grown for food in the Antilles, A. PAIRAULT (*Bul. Assoc. Chim. Sucr. et Distill.*, 18 (1900–1901), No. 1–2, pp. 77–84).—Descriptions and analyses are given of the following plants: Yams (*Dioscorea alata*, *D. trifida*, *D. tuberosa*), Brazil cabbage (*Xanthosma sagittifolium*), taro (*Caladium esculenta* or *Colocasia antiquorum*), banana (*Musa paradisiaca*), breadfruit (*Artocarpus incisa*), manioc cassava (*Manihot utilissima*), and sweet potatoes (*Ipomoea batatas*, or *Batatas edulis*). The percentage composition of the breadfruit follows: Water, 46.21; protein, 2.34; fat, 0.40; starch, 41.42; crude fiber, 4.20; ash, 1.78, and undetermined, 3.65.

Hibiscus esculentus [gumbo], A. ZEGA (*Chem. Ztg.*, 24 (1900), No. 81, p. 871, fig. 1).—Analyses are reported.

Strong and weak flours, F. B. GUTHRIE (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 863–869).—A general discussion of gluten and its relation to bread making.

Yeast as a food and food accessory and its examination under a pure-food law, S. ROHRER (*Ztschr. Untersuch. Nahr. u. Genussmth.*, 3 (1900), No. 11, pp. 756–763).—The methods of examining yeast are described. The author insists that those in use are not satisfactory, and that a method fair to both manufacturer and consumer is needed.

The jam and marmalade industry and sugar consumption in England, P. DEGENER (*Arb. Deut. Landw. Gesell.*, 1900, No. 44, pp. 40; *abs. in Ber. Deut. Bot. Gesell.*, 9 (1900), No. 8, pp. 390, 391).—A descriptive article.

Concerning new food preparations, C. EHLMANN and K. KORNAUTH (*Ztschr. Untersuch. Nahr. u. Genussmth.*, 3 (1900), No. 11, pp. 736–739).—Investigations which

are described in detail show that such food preparations as somatose, meat extract, etc., are quite free from micro-organisms.

Diet of peasants, ROUXEL (*Jour. Hyg.*, 25 (1900), No. 1254, pp. 313-315).—A general and descriptive article.

The digestibility of protein in bread, F. H. CURTISS (*Amer. Phys. Education Rev.*, 5 (1900), No. 3, pp. 221-234).—In experiments in which the author himself was the subject he studied the digestibility of baker's and homemade bread, graham bread, and entire wheat bread, the time required for the digestibility of different sorts of bread being taken into account as well as the thoroughness of digestion.

The lecithin content of milk and its relation to the relative weight of the brain of nurslings, R. BURROW (*Ztschr. Physiol. Chem.*, 30 (1900), No. 6, pp. 459-519).—Investigations on the lecithin content of milk and the brain, which the author believes indicate a relationship between the two.

The influence of acids on the amylolytic action of saliva, G. A. HANFORD (*Amer. Jour. Physiol.*, 4 (1900), No. 5, pp. 250-260).—"The chief object of this note has been to point out that it is impossible to designate any percentage of acid or alkali which inhibits salivary digestion in a definite degree. The character of the action is dependent also upon the absolute amount of saliva and the attendant variation in the quantity of proteid matter present. Whenever free hydrochloric acid is present, inhibition—more or less complete—is certain to result."

A contribution to the subject of peptic digestion, H. MALFATTI (*Ztschr. Physiol. Chem.*, 31 (1900), No. 1-2, pp. 43-48).—A brief account of experimental methods.

Note on the recent report of V. Henriques and C. Hansen on fat absorption, E. PFLÜGER (*Arch. Physiol. [Pflüger]*, 82 (1900), No. 7-8, pp. 381-383).—A critical and controversial article.

The ability of soaps to dissolve colors soluble in fat, J. NERKING (*Arch. Physiol. [Pflüger]*, 82 (1900), No. 9-10, pp. 538-540).—A contribution to the subject of the digestibility of fat.

Contributions to the physiology of creatinin, I. A. GREGOR (*Ztschr. Physiol. Chem.*, 31 (1900), No. 1-2, pp. 98-118).—The author thinks it probable that creatinin is the product of a specific muscle metabolism and represents the cleavage of material corresponding to muscular action.

Yield and preservation of agricultural feeding stuffs, C. BÖHMER (*Ernten und Conservirung der landwirtschaftlichen Futtermittel*. Berlin: P. Parey, pp. 178, figs. 26; rev. in *Ber. Deut. Bot. Gesell.*, 9 (1900), No. 5, pp. 397, 398).—A handbook:

Analyses of fodders and feeding stuffs, F. G. BENEDICT (*Connecticut-Storrs Sta. Rpt. 1899*, pp. 209-215).—Analyses of a number of feeding stuffs are reported, including brome grass, meadow fescue, orchard grass, timothy, soy bean fodder, silage corn (Ohio white dent), stover of white flint corn, soy bean seed, and white flint corn kernels. Most of the materials were samples of crops grown in plat experiments conducted by the station for the purpose of studying the effects of different kinds and amounts of nitrogenous fertilizers upon the yield and composition of different crops (see pp. 1028).

Reports of inspectors of stock for year ended March 31, 1900, T. A. FRASER (*New Zealand Dept. Agr. Rpt. 1900*, pp. 57-126, pls. 7).—This contains the usual matter regarding live stock and brief notes on the subject from the different districts of New Zealand. Among other matters ostrich farming is described.

Experiments in sheep breeding, T. WINTER (*Agr. Gaz. [London]*, 52 (1900), No. 1398, p. 246).—A brief account of cross-breeding experiments.

Information concerning the Angora goat, G. F. THOMPSON (*U. S. Dept. Agr., Bureau of Animal Industry Bul. 27*, pp. 94, pls. 18, fig. 1).—From a large number of sources the author has compiled information on the origin and history of Angora

goats, their use, places adapted to their culture, the care which they require, the building up and management of a flock, shearing and shedding, diseases, and other topics, including statistics.

Profitable production of lean bacon, J. M. HARRIS (*Jour. British Dairy Farmer's Assoc.*, 15 (1900), pt. 1, pp. 7-15).—The requirements for the successful raising of pigs for bacon for the English market are discussed and experiments undertaken by the Wilts County Council and private enterprise are briefly reported. The author's summary follows:

"To produce at the greatest profit the best pigs for the production of prime quality lean bacon, the farmer is recommended: (1) To breed his pigs from Large Yorkshire Whites or from these and pure Berkshires; never from crossbreds. (2) To house his fattening pigs in dry, warm, well-ventilated styes which allow of easy cleaning. They should be placed, if possible, in a sheltered and sunny position. (3) For fattening, to soak the meal used in cold water, to use barley meal as the staple food, and to supplement this, as far as possible, by fresh, separated, skim, or buttermilk, at the rate of about 1 gal. per pig per day, and, when procurable, by boiled potatoes also, not more than 3 or 4 lbs. per pig per day.

"Where cheese is made, it would be well to supplement the barley meal and whey by about 1 lb. of bean or pea meal per pig per day.

"Where dairying is not carried on, bran, toppings, bean meal, or pea meal may be used with care as a substitute for milk; but the dairy farmer has undoubtedly a great advantage in the profitable production of the class of pig required for making the best quality lean bacon."

Pigs at the Hawkesbury Agricultural College, G. VALDER (*Agr. Gaz. New South Wales*, 11 (1900), No. 10, pp. 870-877, pls. 7).—A test on the comparative value of bacon breeds is reported, but definite conclusions are not drawn. Bacon curing is described.

Report of poultry division, D. D. HYDE (*New Zealand Dept. Agr. Rpt. 1900*, pp. 264-275, figs. 9).—The work of the division during the year is described briefly, and directions given for marketing poultry, etc.

Petits poussins ["broilers"], G. A. PALMER (*Jour. British Dairy Farmers' Assoc.*, 15 (1900), pt. 2, pp. 113-119).—The raising of chickens for use as "broilers" has been practiced for centuries in Belgium and France, and the author describes the breeds used and the methods followed. Directions are also given for attractive dressing and marketing of this class of poultry.

DAIRY FARMING—DAIRYING.

The influence of feed and care on the individuality of cows, C. F. DOANE (*Maryland Sta. Bul. 69*, pp. 31-60, pls. 7).—Several years ago the station purchased a herd of grade cows to represent as nearly as possible the average dairy herd found in the State. The record of the cows as to history, feeding, and production previous to their purchase by the station was very incomplete. The attempt was made to increase the productive capacity of the individual cows in the herd by systematic feeding and good care extending over a number of years. The rations fed varied from time to time, and were not uniform for the herd. No attempt was made at forcing. All received the same care. Records of 10 of the cows by lactation periods for 2, 3, or 4 years are tabulated and discussed. Notes are given on the history and feeding of each. Illustrations from photographs are given

of 7 of the cows. The following table gives a summary of some of the data obtained:

Average record of grade dairy herd for several lactation periods.

Cow.	Lactation periods.	Record first period.			Maximum record any period.		
		Yield of milk.	Fat content of milk.	Yield of butter.	Yield of milk.	Fat content of milk.	Yield of butter.
	No.	Pounds.	Per cent.	Pounds.	Pounds.	Per cent.	Pounds.
No. 1.....	4	4,004	5.5	258.3	6,091	5.5	370.0
No. 2.....	4	3,461	4.7	190.3	4,729	5.1	269.9
No. 3.....	2	4,122	3.4	155.6	5,051	3.5	208.9
No. 4.....	3	5,192	3.5	215.4	6,163	3.6	257.1
No. 7.....	4	4,537	4.9	258.8	6,134	5.5	362.2
No. 9.....	2	5,114	4.5	267.0	5,114	4.5	267.0
No. 10.....	3	6,097	3.7	263.0	6,995	4.5	348.3
No. 15.....	4	4,035	3.8	182.9	7,995	4.3	359.2
No. 28.....	3	6,357	3.9	293.4	6,828	4.1	315.9
No. 29.....	3	4,653	4.9	264.4	5,465	5.0	321.2

The author discusses the results as showing the effect of feeding and care upon the development of the cows, noting in this connection results obtained at the New York Cornell Station in feeding grain to young cows on pasture (E. S. R., 2, p. 369).

"No very material results could be noticed the first year from the extra feed and care the herd received, but through subsequent years there seems to be a steady improvement. Judging from the records of these cows, it is a question if the quality of a dairy cow does not depend almost as much on the feeding as on the breeding. It is also a question if cows which have a more or less pronounced beef tendency, or at least would not be called good material from which to build up a dairy herd, can not with proper management be developed into profitable dairy cows."

The bacterial condition of city milk and the need of health authorities to prevent the sale of milk containing excessive numbers of bacteria, H. W. PARK (*Science, n. ser.*, 8 (1901), No. 322, p. 322).—During the coldest weather the milk supply of New York is said to average about 250,000 bacteria per cubic centimeter, during cool weather about 2,000,000, and during hot weather about 5,000,000. This does not apply to the specially-treated milks, which contain from 5,000 to 20,000 bacteria, according to the season. Regarding the harmfulness of these bacteria the author cites the universal clinical experience "that a great number of children in cities sicken on the milk supplied in summer; that those who are put on milk that is sterile or contains few bacteria, as a rule, mend rapidly, while those kept on the impure milk continue ill or die." The author questions whether in the present state of knowledge it is possible for health boards to set a limit to the number of bacteria which milk may contain and above which its sale should be prohibited; but he urges the importance of the authorities giving attention to this matter with a view to securing an improvement through the farmer and the middleman.

The vitality of pathogenic and other micro-organisms in milk, F. VALAGUSSA and C. ORTONA (*Ann. Ig. Sper.; abs. in Nature*, 63 (1901), No. 1634, p. 404).—The action of sunlight on bacteria in milk was investigated, and as was to be expected from the opacity of the liquid no deleterious effect was detected, except in the case of those varieties which live on the surface of liquids and were, therefore, not shielded from the sunshine. Another point of interest investigated was the effect of inoculation into milk upon the elaboration of toxins by the diphtheria bacillus. It was found that although this bacillus produced toxin when grown in milk, its strength was less than when grown in other culture media; moreover, a marked increase in the strength of the toxin was noted when the cultures were kept in a cool cellar instead of at the ordinary temperature of the laboratory. The exact thermal death point of the tubercle bacillus in milk was also reinvestigated, the authors concluding that exposure to temperatures of 60, 70, or 80° C. is insufficient to guarantee the destruction of this bacillus in milk. Milk freshly drawn from the cow, with precautions insuring its sterility, was found to afford a better culture medium for bacteria than after it had been artificially sterilized by heating to 100° C. A bibliography of the existing literature on the subject is appended to the article.

Pathogenic microbes in milk, E. KLEIN (*Jour. Hyg. [Cambridge]*, 1 (1901), No. 1, pp. 78-95).—From an examination of 100 samples of milk from country dairies, 7 were found by inoculation tests to contain virulent tubercle bacilli; 8 samples contained *Bacillus pseudo-tuberculosis*. A series of observations carried out for the purpose of testing the viability of the tubercle bacillus in milk showed that this organism grows well in milk kept at a temperature of 37° C. In one sample of milk the tubercle bacillus of diphtheria was found, and proved to be virulent when inoculated into the guinea pig. *Bacterium diphtheroides* was also found in one sample.

From the secretion of diseased udders the author isolated a number of forms of streptococcus, which were found to vegetate readily on the surface of the gelatin and also in milk at a temperature of 37° C. In 1 sample a pathogenic yeast was found, apparently differing in cultural and physiological characteristics from the torula which had previously been obtained from human cancer. When inoculated into guinea pigs, it produced unusually large tumors. The organism developed well on gelatin, alkaline agar, blood serum, and in milk.

The distribution of the tubercle bacillus and pseudo-tubercle bacillus in milk, and the biology of the tubercle bacillus, E. KLEIN (*Centbl. Baktr. u. Par., 1. Abt.*, 28 (1900), No. 4-5, pp. 111-114).—The author made an examination of 100 samples of milk from the London market in the condition in which it is received from the surrounding

country. The milk was allowed to stand in an ice chest for from 20 to 24 hours. This method was found to be as satisfactory for getting rid of foreign bodies as that of the centrifuge. Two forms of bacteria were found in the milk samples, one resembling in all respects the tubercle bacillus and being acid proof, the other form being too short and thick for the true tubercle bacillus. The latter form of bacillus did not produce tuberculosis when injected into experimental animals. It was found by experiments that the virulence of the tubercle bacillus may be considerably increased by repeated culture in milk. Cultures of tubercle bacillus which the author had maintained upon glycerin agar for 12 years were inoculated in milk, with the result that within a week clumps of developing bacilli were noticed with the characteristic appearance of the tubercle bacillus. Guinea pigs inoculated with this culture developed true cases of tuberculosis.

Experiments with pasteurizing apparatus, 1900, V. STORCH, P. V. F. PETERSEN, and L. C. NIELSEN (*47. Rpt. Kgl. Vet. Landbohøjskoles Lab. Landokon. Forsøg [Copenhagen], 1900, pp. 64*).—The main part of this report is given up to an account of the working, under ordinary creamery conditions, and tests of the maximum capacity, of 3 different forms of pasteurizing apparatus made by Danish manufacturers in accordance with suggestions laid down in a previous report of this station (E. S. R., 11, p. 887).

The results show in general that the apparatus satisfactorily meets the requirements of modern Danish creameries. A table is worked out showing the amount of heating surface required to raise 10,000 lbs. of milk per hour 1° C. from 0 to 99° . The trials made show that an apparatus constructed according to the principles explained in the report, which has a heating surface of 15,000 sq. cm., will raise 11,200 lbs. (Danish) of milk per hour from 40 to 85° C., which has been estimated to be a saving of about 40 per cent in steam consumption over that required by the older forms of pasteurizing apparatus.

Destroying foam in centrifugal skimming.—In skimming milk by the centrifugal process foam may be formed in three places, in the cream separator, in the skim milk pump, and in the older forms of pasteurizing apparatus. From observations made in the earlier investigations it seemed likely that the improved pasteurization apparatus might act as a foam destroyer, and further trials showed that after certain changes were made in the apparatus it acted satisfactorily in this respect. If the weight of the foamless milk be assumed to equal 1, the milk as received from the separators in one series of trials weighed on the average 0.71, and from the skim milk pump 0.65, while milk drawn from different heights of the pasteurizing apparatus (from below upward) weighed 0.90, 0.95, 0.97, 0.98, and at the outflow of the apparatus, 0.94. In another apparatus tried the following

average figures were obtained: From separator, 0.72; from skim milk, 0.62; from different parts of the apparatus, 0.88, 0.96, 0.97, and 0.98, and at the outflow, 0.97.

Keeping trials with pasteurized skim milk.—The keeping qualities of skim milk pasteurized at 85 to 88° C. and at 97 to 99° C. were determined in a number of trials, and comparisons made with raw skim milk. The milk was cooled to different temperatures or treated in different ways after the heating. The samples were kept in stoppered bottles at ordinary room temperature, and the time noted when the milk could still be boiled without curdling. The average results are given in the table below, the second column showing those for 3 creameries and the third those at one other:

Length of time skim milk kept after pasteurizing.

	When heated to 85-88°.	When heated to 97-99°.
	Hours.	Hours.
Raw skim milk pasteurized at 40° C	12	11
Pasteurized skim milk direct from separator	59	59
Pasteurized skim milk cooled to 50° C. and sampled	48	48
Pasteurized skim milk cooled to 50° C., poured in milk can, and sampled.....	24	25
Pasteurized skim milk poured directly into milk can and sampled.....	55	60
Pasteurized skim milk cooled to 10° C. and sampled	51	50
Pasteurized skim milk cooled to 10° C., poured into milk can, and sampled	31	28
Pasteurized skim milk poured directly into milk can and sampled.....	56	60

The results show that the easiest way to sterilize transportation cans is to fill them with the milk at the temperature of pasteurization (85° C. or above), an 80-lb. can of milk cooling only 2 to 3 degrees if the can is filled full, and 4 to 5 degrees if only half filled; and that cooled pasteurized milk can not safely be kept in nonsterilized transportation cans.—F. W. WOLL.

A view of the present state of the dairy industry in Russia, P. PAKHOMOFF (*Soc. Imp. Agr. Moscow, 1900, pp. 50, figs. 6*).—A publication issued for distribution at the Paris Exposition of 1900.

Science in relation to dairying in New South Wales, M. A. O'CALLAGHAN (*Agr. Gaz. New South Wales, 12 (1901), No. 1, pp. 139-143, figs. 3*).—A history of the progress of dairying in the section indicated.

Development of the dairy cow, C. S. PHELPS (*New York Produce Rev. and Amer. Creamery, 14 (1901), No. 30, pp. 26-31*).—An address before the Connecticut Dairy-men's Association.

An experimental milk supply, W. ROBERTSON (*Public Health, 13 (1901), No. 6, pp. 412-421*).—A paper read before the Society of Medical Officers of Glasgow, Scotland, concerning the results reached by the methods employed in improving the city milk supply.

The composition of Indian cows' and buffaloes' milk, J. W. LEATHER (*Analyst, 26 (1901), No. 299, pp. 40-42*).—The fat content of the cows' milk was high, varying from 4 to 6 per cent. That of buffaloes' milk was very high, 7 and 8 per cent being common. Butter from the cows' milk was very pale yellow; from the buffaloes' milk, quite white.

Variations produced in the acidity of milk by heating, H. HÖFT (*Milch Ztg.*, 30 (1901), No. 7, p. 103).—By heating milk from 50° C. to boiling the acidity was reduced from 4 to 10 per cent. The amount reduced was variable but in general increased with the degree of heat applied.

Goats' milk, T. ZAMITT (*Rev. Internat. Falsif.*, 12 (1899), pp. 44, 45; *abs. in Jahresber. Thier Chem.*, 29 (1899), p. 241).—An average analysis of the milk of goats on the Island of Malta shows specific gravity 1.032, fat 5 per cent, ash 0.89 per cent, dry matter, including fat, 15 per cent.

Artificial milk, MARSAC (*Ind. Lait.*, 26 (1901), No. 5, pp. 35, 36).—The chemical and mechanical means of rendering cows' milk more like human milk in composition are described, and the employment of such milk in feeding children is discussed.

Destroying tubercle bacilli in milk, MORGENROTH (*Hyg. Rundschau*, 10 (1900), pp. 865-868; *abs. in Chem. Centbl.*, 72 (1901), I, No. 2, p. 128).—By experiments it was found that milk infected with tubercle bacilli was rendered sterile by heating to 70° C. for from 10 to 30 minutes, or to 100° C. for from 3 to 5 minutes. After heating, the milk was cooled quickly. The same result was attained by keeping the milk at a temperature of 55° for 3 hours. Keeping it at that temperature for 2 hours did not render the milk sterile.

Classification of dairy bacteria, H. W. COXN (*Connecticut Storrs Sta. Rpt.* 1899, pp. 13-68).—Detailed descriptions, including morphology and cultural and biochemical characteristics, are given of over 100 species of bacteria isolated by the author from dairy products during the last 10 years, together with an account of the collection of the bacteria, methods of isolation and study, and the classification and naming of the species. The bacteria are arranged in 10 groups, and tables devised for the rapid identification of the species are given. The species or groups of closely related forms most commonly found were *Bacillus acidi lactici*, *B. lactis aerogenes*, and *Micrococcus lactis varians*. A list of references upon systematic bacteriology with special reference to dairy species is given.

Inspection of Babcock milk-test bottles, W. H. JORDAN and G. A. SMITH (*New York State Sta. Bul.* 178, pp. 97-103).—The New York law relative to the testing of bottles used in the Babcock test at creameries and cheese factories is given and briefly discussed. The method followed at the station in the testing of the bottles is given. Of 2,259 bottles tested, 76 were rejected. A list of creameries and individuals sending bottles for examination in compliance with the law is given.

The volatile fatty acid content of Netherlands butter, L. T. REICHER (*Ztschr. Angew. Chem.*, 14 (1901), No. 6, pp. 125-128).—Analyses showing the Reichert-Meißl number of butters examined covering several years.

Making sweet-cream butter (*New York Produce Rev. and Amer. Creamery*, 14 (1901), No. 29, pp. 10-14).—Reports from dairymen and others on the making and marketing of butter from sweet cream.

The Belgian law covering the manufacture and sale of oleomargarine, J. WAUTERS (*Bul. Assoc. Belge Chim.*, 14 (1900), No. 11-12, pp. 453-475).—A reprint of the law, and comments covering some results of analysis of butter and butter substitutes in Belgium.

The chemical changes in the manufacture and ripening of cheese, J. R. GREEN (*Jour. Roy. Agr. Soc. England*, 3, ser., 11 (1900), pt. 4, pp. 674-693).—This is a résumé of the subject of the ripening of cheese, including the changes which take place and the modern views regarding the causes of these changes, development of special flavors, etc.

Changes in the fat during the ripening of soft cheeses, G. FASCETTI (*Staz. Sper. Agr. Ital.*, 33 (1900), No. 5, pp. 430-435).—The changes that occur in the fat during the ripening of soft cheeses consist largely in the formation of soluble fatty acids. These changes are more pronounced in pure cheese than in filled cheese.

Melun cheese, A. VIVIEN (*Ind. Lait.*, 26 (1901), No. 6, pp. 43-45).—A description of melun cheese, together with methods of manufacture and analyses of the product.

Cheese from goat milk, B. C. BUFFUM (*Amer. Agr.*, 67 (1901), No. 12, p. 361).—The present progress and the possibilities of the manufacture of cheese from the milk of goats.

Making cheese from heated milk, J. KLEIN and A. KIRSTEN (*Milch Ztg.*, 30 (1901), No. 3, pp. 35-37).—In the experiments of making cheese from milk heated to 90° C. the curd and cheese secured was greater than with milk not heated, owing to a higher whey content.

VETERINARY SCIENCE AND PRACTICE.

Leucocytosis in experimental infections, E. SCHLESIGNER (*Ztschr. Hyg. u. Infectiouskrank.*, 35 (1900), No. 3, pp. 349-419).—This article contains a detailed account of a large number of experiments made by the author for the purpose of determining the effect of hypodermic inoculations of various pathogenic bacteria upon the number of the leucocytes. Among the bacteria with which experiments were made may be mentioned the organisms of pneumonia, diphtheria, anthrax, and tetanus. The total number of leucocytes and the relation of the polynuclear cells to the lymphocytes was found to vary exceedingly in rabbits. The number of white blood corpuscles varied from 1,000 to 2,000 per cubic centimeter in health. A reduction of the number of leucocytes after hypodermic injections was noted in only one case, after about 4 hours. It was found that the appearance, intensity, and duration of hypoleucocytosis were variable, and that there was no relationship between this process and the quantity or virulence of the bacterial culture. In the process of leucocytosis the lymphocytes were most affected, while the polynuclear cells were only slightly decreased in number. A hyperleucocytosis was often the only symptom upon inoculation. In cases in which recovery took place the hyperleucocytosis reached its maximum on the second or third day, and the number of leucocytes decreased to the normal very rapidly. In fatal cases the behavior of the white blood corpuscles was extremely variable.

In inoculations of anthrax cultures, leucocytosis exhibited two phases, one in which the number of white blood corpuscles was slightly decreased in cases which finally recovered, and somewhat increased in fatal cases, and the second phase in which there was a great increase in the number of white blood corpuscles in fatal cases and a slight increase in convalescent cases. In immunizing experiments with anthrax it was found that after the first injection of anthrax vaccine a rather marked hyperleucocytosis took place.

The relative susceptibility of the domestic animals to the contagia of human and bovine tuberculosis, R. R. DINWIDDIE (*Arkansas Sta. Bul.*, 63, pp. 37-65).—In this bulletin the author gives the results of further experiments along the same line as those reported in

Bulletin 57 of the Arkansas Station (E. S. R., 11, pp., 689-691). In the previous experiments he used a crude tubercular material of human and bovine origin, while in the present tests pure cultures of the tubercle bacillus from these 2 sources were used for inoculation purposes. During these experiments 10 cultures, 6 of bovine origin and 4 of human origin, were employed, 8 or more cattle, sheep, and pigs being subjected to the test. The cultures were in all instances isolated by a preliminary passage through the guinea pig. As the culture medium the author used 6 per cent glycerin beef serum, coagulated and sterilized at temperatures from 80° to 90° C. In sheep and pigs inoculations were made in the body cavity. In cattle the inoculations were made in this manner, and also directly into the substance of the lungs. Seven calves, ranging in age from 2 to 17 months, were inoculated with sputum cultures, 5 in the body cavity, 1 in the lung, and 1 in the trachea. None of these animals suffered from any striking impairment of health during periods of from 5 to 18 months, when they were under observation. Three failed to respond to the tuberculin test, 1 gave a doubtful reaction, and 3 responded positively. The reaction to the tuberculin test disappeared in all the calves within 4½ months after inoculation. In 2 cases the animals were reinoculated with bovine cultures 1 year after receiving sputum cultures. Post-mortem examinations showed conclusively that the numerous tubercles were of recent origin, and had been caused by the recent inoculations. These experiments indicated that repeated injections of tuberculin and previous inoculations with sputum cultures had no immunizing effect, and that the sputum cultures apparently produced only a temporary form of the disease. The author believes that whatever may be determined the most common means of natural infection in cattle, unsanitary surroundings are in nearly all cases of great importance.

The author used 6 sheep in determining the effect of sputum cultures on these animals. The sheep which survived were kept for about a year and examined, after having given a positive reaction to tuberculin. Similar inoculations were made on sheep with bovine cultures. The results obtained from these comparative tests were similar to those obtained with cattle, with the exception that the sheep exhibited a rather high degree of susceptibility to tuberculosis produced by inoculation.

In previous experiments on pigs, no excess of virulence of the bovine tubercle over that of man was noted. In comparative tests with pure cultures, the difference in the effects of the sputum and bovine cultures were almost as well marked as in the case of sheep.

The general results of these experiments may be summarized as follows: Pigs, sheep, and cattle possess a varying degree of susceptibility to tubercle bacillus of human origin, cattle being most resistant and pigs least so. In pigs only were genuine cases of chronic tuberculosis developed by inoculation with human tubercular material.

Sheep were found to be somewhat more susceptible than cattle, as evidenced by the larger lesions and the permanence of the tuberculin reaction. All three species were found to be highly susceptible to cultures of bovine origin. In the case of cats, only two were tested. The effects were about the same, being slight in either case. The susceptibility to tuberculosis produced by inoculation in the domestic animals does not correspond strictly to the extent of the naturally acquired disease. Among the other factors which may be important in determining this matter, the author attributes weight to the bad ventilation in stables.

Tuberculous cows and the use of their milk in feeding calves, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1899, pp. 150-167*).—The author continued experiments with 4 cows upon which a report has been previously noted (E. S. R., 11, pp. 890, 891). These cows had been under observation for $3\frac{1}{2}$ years. Detailed statistics concerning the history of the cows and of the calves which were fed upon their milk are presented in tabular form. One of these cows gave no reaction to the tuberculin test since January, 1897, a period of $3\frac{1}{2}$ years. The second cow responded to the test in December, 1899, but failed to respond on March 20, 1900. The third cow showed a reaction in June, 1899, but did not respond when tested in December, 1899, and on March 20, 1900. The fourth cow failed to respond to tests which were given in the years 1899 and 1900.

During a greater portion of the $3\frac{1}{2}$ years, the milk from the 4 tuberculous cows was fed to calves. In some cases the calves were fed until they were a year or more of age; and in most of the experiments they were confined in the same stable with the cows and exposed to the contraction of tuberculosis by ordinary contagion. A detailed history is given of each feeding experiment, the general results of which may be summarized as follows:

During the first 2 years only 1 secondary case of tuberculosis developed. This case appeared about 25 months after the cows were purchased. During this time 4 animals were fed from the milk of the cows for periods ranging from 12 to 18 months. At the same time the experimental calves were closely associated with the cows. The experience of the first 2 years indicated, therefore, that when tuberculosis exists in a cow in its incipient stages, the liability of its transmission by milk or otherwise to calves which are associated with the cows is quite limited. During the succeeding year and a half different results were obtained. From August, 15, 1898, to March 20, 1900, 5 animals were fed upon the milk of these cows, and all 5 contracted tuberculosis. Two of these cases developed in calves 3 months old, and the other 3 in calves from 12 to 18 months old. The physical condition of the cows indicated that the disease had become much more generalized, at least in 3 cases.

During the first 2 years it was impossible to diagnose tuberculosis in the cows by physical symptoms, except doubtfully in one case. During the following year and a half, however, physical examination gave good evidence of the disease in 3 out of the 4 cows. The fact that no case of tuberculosis appeared in the calves until they had been fed upon the milk of these cows for from 1 to 1½ years, and had been almost constantly associated with them, indicates that there is little danger from the transmission of tuberculosis during its earlier stages.

Serum diagnosis of tuberculosis in cattle, S. ARLOING (*Jour. Med. Vet. et Zootech.*, 5. ser., 4 (1900), pp. 449-458).—The author conducted 3 series of experiments for the purpose of determining the action of blood serum in agglutinating quantities of tubercle bacillus. In the first series the serum was prepared from the blood of calves, in the second from the blood of healthy cattle, and in the third from the blood of adult tuberculous cattle. In the first series of experiments the blood of 30 calves was tested with reference to its agglutinating power; the calves were from 5 to 8 weeks old. From none of the calves was a serum obtained which would agglutinate quantities of tubercle bacillus, even in the proportion of 1 drop of the serum to 2 drops of the culture. In the second series of experiments 50 adult cattle were utilized, from which serum was prepared and mixed with homogeneous cultures of the tubercle bacillus, in the proportions of 1 to 5 and 1 to 10. In no case did the serum produce agglutination in the proportion of 1 to 10, while in the proportion of 1 to 5 the serum from 24 out of 50 subjects had a more or less pronounced agglutinating effect. In the third series of experiments the author studied the serum of 70 tuberculous cattle. Of this number of experimental animals 69 furnished a blood serum with agglutinating power when mixed with quantities of the tubercle bacillus in the proportions of 1 to 10 and 1 to 20. In the remaining cases the agglutinating power was not pronounced in mixtures of 1 to 5. The author attempted to determine whether there was a definite relation between the intensity of the agglutinating power and the extent of the tubercular infection. Such relation was not apparent. From these experiments it is concluded that, as a general rule, the blood serum of a tuberculous animal has the power of agglutinating the tubercle bacillus in homogeneous cultures in the proportion of 1 to 10. An animal of which the blood has such power may therefore be considered tuberculous. This test may be used in checking the results from tuberculin tests and may also be applied independently.

The hereditary transmission of tuberculosis through the placenta, G. D'ARRIGO (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 20, pp. 683-691).—In order to secure evidence of the hereditary transmission of tuberculosis, the author conducted two series of experiments, in one of which guinea pigs were allowed to become pregnant after

inoculation with tubercle bacillus, while in the other series the guinea pigs were inoculated during pregnancy. The results obtained may be summarized as follows:

Guinea pigs which became pregnant during the process of tuberculosis, aborted in only a few cases. In the placenta and foetus of guinea pigs which were killed on the sixteenth day of pregnancy, tubercle spores and bacilli were found in various lesions. From the location of these lesions it would appear that the tubercle bacillus made its way through the placenta from the blood of the mother and was enabled to establish itself in the tissue of the foetus only after the lesions had been produced by the circulating tuberculin of maternal origin. In the young of tuberculous guinea pigs, pathological lesions were found rather abundantly, especially in the liver. The young animals soon became emaciated and died ultimately of tuberculosis. A bibliography of the subject is appended to the article.

Experimental tubercular mammitis in cows and goats during lactation, E. NOCARD (*Rev. Med. Vet., Paris, 8. ser., 7 (1900), No. 23, pp. 721-727*).—It had already been determined that inoculation of anthrax cultures into the milk sinus produces death within a few days and that a similar inoculation in animals which had been previously vaccinated against anthrax did not produce the disease in such animals; but it was observed that the anthrax bacillus persisted indefinitely in the milk ducts in a virulent form, and that ultimately the animal succumbed to toxins produced by these bacilli. The author had, therefore, already established the possibility of the persistence and multiplication of bacilli in the secretions of an animal which was perfectly immunized against the bacillus. The absence of an antitoxic power of an immunized organism was also noted. In the experiments with the tubercle bacillus, the author made use of a cow and a goat in the period of lactation. For producing inoculation it was found sufficient to inject a small quantity of a virulent culture of the tubercle bacillus in such a manner as not to produce any lesion of the mucous membrane. A tubercular mammitis of rapid course was produced and death resulted within a few weeks. A study of these cases, however, demonstrated that death was the result of intoxication, not of a generalization of tuberculosis. A high temperature was shown in both the cow and goat, being from 40 to 41° C. in the former and 40 to 42° in the latter.

The author concludes from his experiments that the active mammary gland is the most favorable of all living tissues as a culture medium for tubercle bacillus and that for studying tubercular intoxication it is sufficient to make inoculations into the teat of an active mammary gland.

The diagnosis of anthrax and the destruction of anthrax carcasses, MEYER (*Berlin. Thierärztl. Wchnschr., 1900, No. 49, pp. 579-582*).—In a series of observations on the reliability of various

methods for diagnosing anthrax, the author found that the bacteriological method and the microscopical method of recognizing the anthrax bacillus in the blood are rendered difficult when the anthrax carcass is allowed to decompose to some extent before the examination is made. In order that the microscopical examination of the blood may be reliable, such examination should be made immediately after death. In the hands of experienced practicing veterinarians, mistakes in the diagnosis of anthrax are perhaps seldom made from judging external symptoms; but in order that the diagnosis should be certain, the author believes that a microscopical examination of the blood should be required by law. It is recognized that the difficulties of preventing the spread of anthrax are increased after opening the bodies of dead animals. Detailed directions are therefore given for the destruction of such carcasses.

Experimental researches on symptomatic anthrax; immunization, E. LECLAINCHE and H. VALLÉE (*Ann. Inst. Pasteur*, 14 (1900), No. 8, pp. 513-534).—The author conducted experiments in the immunization of animals against this disease according to three different methods—inoculation with virus vaccine, pure cultures, and immunizing serum. It had already been shown that inoculation with cultures of *Bacterium chauvæi* heated for 2 or 3 hours to a temperature of 80 to 85° C. did not kill the experimental animals. The virus vaccine of Lyon is prepared from virulent fluid collected from the tumors of infected animals. This fluid when desiccated at a temperature of 37° C. gives a brown powder which incloses virulent spores. One part of the powder is then mixed with two parts of water and the vaccine for the first inoculation is obtained by heating for 7 hours at a temperature of 100 to 104° C. The vaccine for the second inoculation is obtained by heating at a temperature of 90 to 94° C. for the same length of time.

The tumors of infected animals occasionally contain other organisms beside that of symptomatic anthrax. In order to prepare pure vaccines it is necessary to make use of blood drawn from the heart or large vessels immediately after death. In the use of pure vaccines it was found that a vaccine obtained by heating to a temperature of 102° may be inoculated in young guinea pigs in doses of 0.05 gm. without producing death. The vaccine obtained by heating to a temperature of 92° C. killed guinea pigs when inoculated in the same sized doses. Cattle which were inoculated with heated cultures acquired an immunity which enabled them to resist subsequent inoculation with virulent cultures in doses of 0.02 gm. Animals which were inoculated successively with heated and nonheated cultures were found to possess complete immunity. Nine days after intramuscular inoculation of virulent fluid from infected animals, it was impossible to note any reaction, while the check animal died within 36 hours.

The authors conclude from their experiments that powdered vaccines prepared according to Arloing and Cornevin are not attenuated,

and that they contain unmodified spores. Their special properties are supposed to be due to an alteration of the toxin under the influence of heat. It was found possible to prepare pure powdered vaccines. Vaccination of cattle may be effected by the use of pure cultures heated to a temperature of 70° C. for 2 hours. The partial immunity thus produced may be completed by inoculation with a pure culture which has not been subjected to heat. Animals thus treated resist large doses of virulent fluid without reaction. This method has the advantage of being convenient and practical. The horse and goat treated with repeated intravenous injections of virulent fluid or pure cultures produce an immunizing serum which is possessed of preventive properties. It confers only a temporary immunity, and when mixed with virus, neutralizes the effects of the latter without producing permanent immunity.

Practical experience in vaccination against hog cholera, GRAUL (*Berlin. Thierärztl. Wehnschr.*, 1900, No. 49, pp. 577-579).—In the present article, the author confines his attention to the three problems concerning the duration of immunity, indemnity for loss caused by inoculation, and inoculation by stock owners. According to the author's observations, the period of immunity produced by ordinary inoculation methods does not extend beyond 6 or 7 months. It is thought desirable, if possible, to bring about an immunity which will endure for a full year. In some instances, losses occurred as a direct result of preventive inoculation. The author believes that the question of indemnity for such losses must ultimately be regulated in a legal manner. On the question as to whether untrained individuals shall be allowed to inoculate animals, the author takes the position that this is very undesirable. Trained veterinarians are sufficiently numerous in all localities to be readily secured for this work in cases of emergency, and far better and more satisfactory results are obtained when such persons are engaged for the work than when inoculation is left in the hands of more or less irresponsible individuals.

Preventive and curative inoculations against hog cholera, T. KITT (*Monatsh. Prakt. Thierh.*, 12 (1901), No. 2-3, pp. 87-100). The author presents a critical historical account of the various methods which have been adopted in producing immunity against this disease. It is stated that Susserin brings about a cure for hog cholera in many cases, and that when inoculated for protective purposes an effective immunity is produced. The use of attenuated pure cultures of hog-cholera bacillus for producing immunity against the disease is safe only in the hands of trained veterinarians. The substance known as Porcosan has been placed on the market with claims for its power in producing immunity against hog cholera. It was found, however, to contain living hog-cholera bacilli, and is therefore not to be recommended.

The glanders bacillus and glanders tubercle, G. MAYER (*Centbl. Bakt. u. Par., 1. Abt., 28 (1900), No. 20, pp. 673-683, pl. 1*).—The author presents a critical historical review of the literature relating to the structure of the glanders bacillus and the tubercles formed by its action. During his experiments pure cultures of glanders bacillus were injected into the body cavity of guinea pigs. It was found that the floating portion of such cultures could not be relied upon to produce acute cases of glanders. In order to accomplish this it was necessary to employ cultures from agar bouillon, rubbed up in a mortar with sterile butter. After inoculation with material prepared in this way death occurred within from 18 to 42 hours in the case of the most virulent cultures and after from 4 to 11 days in the case of less virulent cultures. In isolated specimens of the glanders bacillus, club-shaped swellings were observed at either end. In clusters of the bacillus club forms were more abundant on rods which occupied a peripheral position. The general appearance and the behavior of the bacillus were the same as in the case of streptothrix. The glanders bacillus was observed to penetrate into the lymphatic vessels and mesenteries. After escaping from the body cavity the bacilli made their way at once into the lymph cavities. In some animals an extensive accumulation of wandering cells was observed in the spleen. Tubercles produced by the glanders bacillus were characterized by the rapid accumulation of such cells, which soon became very similar to epithelial cells. After the formation of such tubercles the tissue is rapidly broken down by the action of the glanders toxin.

Experimental aspergillosis, T. A. ROTHWELL (*Jour. Path. and Bact., 7 (1900), No. 1, pp. 34-52, pl. 1, figs. 4*).—Intraperitoneal, subcutaneous, and dermic inoculations of *Aspergillus niger* and *A. fumigatus* were made by the author in guinea pigs and rabbits. The detailed results of these experiments were tabulated for the purpose of comparison. The majority of experiments were made by means of intraperitoneal injections, this method being considered preferable to intravenous injections on account of the possibility of producing embolism by the latter method. The results of such inoculations consisted essentially in the formation of tubercles of various sizes in different organs. The tubercles consisted in the proliferation of the connective tissue cells which ultimately gave rise to small translucent bodies. During the later stages of development of these tubercles, there was a noticeable infiltration of polynuclear leucocytes. Both species of *Aspergillus* were found to be capable of producing lesions which resembled one another, but injections of *A. fumigatus* caused death while those of *A. niger* did not. Both organisms were shown to be capable of germinating in the living tissues. *A. fumigatus* is considered more pathogenic than *A. niger*.

Investigation of diseases in poultry, E. F. PERNOT (*Oregon Sta. Bul.* 64, pp. 24, figs. 4).—The author made a study of avian tuberculosis in poultry. Experiments in inoculating guinea pigs with tuberculous material from the intestines and liver of a diseased hen gave negative results. In one case where 6 hens died of tuberculosis one was examined and found affected with a generalized form of the disease. The digestive tract was evidently the original focus of infection in this case, as shown by the numerous tubercles in the intestinal walls. These tubercles ultimately break down, and the disease may therefore be spread in the intestinal passages. It is recommended that all fowls which die of tuberculosis should be deeply buried or burned. The author studied also one case of tuberculosis of a hen's leg.

In the treatment of catarrhal roup, the author obtained good results from the use of a 2 per cent solution of permanganate of potash and water. In administering this treatment the head of the fowl was plunged into the solution and held there for a short time. The result of this immersion is ordinarily violent sneezing, which forces the solution through the nasal passages. The same solution may be diluted with 4 times its bulk of water and given to the fowls to drink.

Favus of fowls may be treated by removing the scales from affected birds and applying an ointment made of vaseline and 2 per cent carbolic acid. The treatment recommended for scabies of poultry consists in removing loosened scales by soaking in warm water and soap and the subsequent application of an ointment made of balsam of Peru, at the rate of 1 or 2 drams to 1 oz. of vaseline.

The author reports serious losses among young chickens, especially incubator chickens, from pneumonia and congestion of the lungs. These diseases were apparently brought about from overcrowding in the brooders and from exposure to cold when allowed to come out of the brooder houses. As a remedy for this difficulty, the author recommends any device which will prevent the young chickens from huddling too closely together and becoming overheated. In one instance, where a device of this kind was used, 99 per cent of the chickens were raised. A rather heavy loss of incubator chickens was occasioned in some parts of the State by indigestion, due to improper feeding and to feeding too soon after hatching.

Tetanus, E. MATHEWS (*Jour. Comp. Med. and Vet. Arch.*, 21 (1900), No. 12, pp. 741-745).—The author treated 4 cases of tetanus by hypodermic injections of woorara with good results in 2 cases, while in the other 2 cases the quality of the drug was believed to be inferior.

The source of tuberculosis in farm animals, R. R. DINWIDDIE (*Arkansas Sta. Bul.* 63, popular ed., pp. 69-73).—A brief popular form of Bulletin 63 (p. 1084).

The value of serum reactions for the early diagnosis of tuberculosis, S. ARLOING and P. COURMONT (*Deut. Med. Wchnschr.*, 26 (1900), No. 48, pp. 766-769).—This article contains a report of observations on the agglutinating power of blood

serum from tuberculous patients. A more or less marked agglutination was produced by mixtures of such serum in proportions varying from 1 to 5, to 1 to 20. The most marked agglutination was produced from serum from incipient cases of tuberculosis.

Condemning tuberculous animals, G. MAZZINI (*Gior. R. Soc. Accad. Vet. Ital.*, 49 (1900), No. 49, pp. 1165-1168).—Brief suggestions on the extent to which tuberculous animals should be destroyed.

Tuberculosis in dogs, G. PETIT and J. BASSET (*Rec. Med. Vet., Paris*, 8. ser., 8 (1901), No. 1, pp. 5-13).—This article contains detailed statements of the post-mortem findings in dogs which died of tuberculosis. The authors found evidence of tubercular pleurisy and pericarditis. The liver and kidneys were frequently affected. In the lungs the tubercles ultimately degenerated, leaving a cavity without caseous formation.

The leucocytes in tuberculosis, C. ACHARD and M. LÉPER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 39, pp. 1066, 1067).—In cases of tubercular arthritis the authors found in the serum a predominance of the lymphoid elements, there being 96 lymphocytes, 4 mononuclear, and 2 polynuclear elements to the 100 elements. When tubercular arthritis was produced experimentally, a temporary phase of increase in the number of polynuclear elements was noted, but the mononuclear elements ultimately became much more numerous. The same conditions were found to prevail in cases of generalized tuberculosis produced experimentally by intravenous inoculations.

Results obtained from inoculation against Texas fever, SCHEIBEL (*Monatsh. Prakt. Thierh.*, 12 (1901), No. 2-3, pp. 108-121).—The author presents in a brief form the results thus far obtained by different investigators in producing immunity against this disease. A bibliography of the subject is appended to the article.

Report of 10 cases of parturient paresis treated by potassium iodid, G. H. ROBERTS (*Indiana State Bd. Agr. Rpt.*, 49 (1899-1900), pp. 699-701).—The author tabulates the history of these cases, in which the Schmidt treatment was adopted. Three of the cases died, while the other 7 recovered.

Measures to be adopted in controlling foot-and-mouth disease, J. DUPUY (*Bul. Min. Agr. [France]*, 19 (1900), No. 2, pp. 183, 184).—It is reported that foot-and-mouth disease occurred during the past year in an epizootic form of unusual severity. The present article is in the nature of a circular stating the sanitary measures which promise to give the best results in controlling the disease.

Foot rot in sheep, G. C. BELLINGER (*Agr. Gaz. New South Wales*, 11 (1900), No. 12, pp. 1118, 1119).—Brief notes on the nature and cause of this disease. An abundance of wet grass is believed by the author to be conducive to a somewhat troublesome form of foot rot.

Hog cholera and its treatment, G. D'UTRA (*Bol. Agr. São Paulo*, 1. s. r., 1900, No. 5, pp. 318-331).—The author gives a brief account of the geographical distribution of this disease, together with a discussion of the various names by which it is known in different countries. The different forms are described by means of the symptoms and pathological lesions. Preventive vaccination is recommended as the only means of successfully combating the disease.

Hog cholera cure (*Indiana State Bd. Agr. Rpt.*, 49 (1899-1900), pp. 336, 337).—A brief popular account on the worthlessness of patent medicines in the treatment of this disease and the practical hygienic measures which should be adopted.

Combating swine plague and hog cholera, SCHREIBER (*Berlin. Thierärztl. Wchnschr.*, 1900, No. 50, pp. 589-593).—The author conducted experiments for the purpose of determining whether these two diseases could be produced experimentally at will, and also to determine the relationship of the diseases to each other. Experiments were made on young pigs from 4 to 10 weeks old. These experiments indicated that both swine plague and hog cholera may be produced by intrathoracic and intraperitoneal inoculations and also by feeding with diseased tissue. The author

was unable to produce either hog cholera or swine plague by subcutaneous injections of virulent pure cultures. It was also found that hogs which had recovered from hog cholera possessed no immunity from swine plague; or where such immunity was observed, it was of only short duration.

Dourine of horses, J. MAREK (*Ztschr. Thiermed.*, 4 (1900), No. 6, pp. 401-443, figs. 8).—The author made extended studies of the pathological lesions produced by this disease. Especial attention was given to the brain, spinal cord, and spinal nerves. These studies failed to show any trace of an inflammatory process in any part of the central nervous system. In the posterior columns of the spinal cord a secondary degeneration of nervous tissue was noted. In long-standing cases certain pathological changes were noticed in the peripheral nerves and in the spinal cord, but it is believed that these changes could not be the cause of the symptoms usually observed in cases of dourine.

Malignant œdema in horses, FRÖHNER (*Monatsh. Prakt. Thierh.*, 12 (1901), No. 2-3, pp. 100-103).—The author gives a detailed account of the symptoms and post-mortem findings in this disease in horses.

Dog distemper, E. ZSCHOKKE (*Schweiz. Arch. Tierh.*, 42 (1900), No. 6, pp. 241-248, fig. 1).—The author describes in detail the symptoms of this disease. It is stated that the form which was studied by the author was not what is ordinarily known as dog distemper, but it is correctly called gastritis hemorrhagica. Numerous remedies were tried in the treatment of the disease without striking results. It was found that the most that could be hoped for was an alleviation of the more pronounced symptoms by careful dieting and nursing.

A method of demonstrating the capsule in all species of bacteria, I. BONI (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 20, pp. 705-707).—This method consists in staining the bacteria in carbolfuchsin or other anilin stains, then drying and washing with water and a secondary staining with methylene blue. By this method the author was able to demonstrate the capsule in a considerable variety of bacteria, including the micro-organisms of anthrax and glanders.

The disappearance of the so-called bactericidal action of blood serum on account of the addition of nutritive substances, FINKH (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 20, pp. 694, 695).—The author experimented with the micro-organisms of anthrax, typhus, and cholera. Freshly drawn rabbit serum was used for this purpose, and it was found that by the addition of peptone sugar the serum was rendered entirely inactive toward the anthrax bacillus.

The antibacterial action of the serums of animals treated with arsenic and creosote, E. WIENER (*Compt. Rend. Soc. Biol. Paris*, 52 (1900), No. 39, pp. 1073-1075).—The author conducted experiments on rabbits and dogs. These animals received injections of arsenic and creosote and their serums were later examined with reference to their action toward the micro-organisms of typhus and cholera. It was found that a preliminary treatment with arsenic or creosote considerably increased the action of protective substances which normally exist in the organism.

The theory of disinfection, H. MARX (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 20, pp. 691-693).—The author had previously demonstrated that the virulence of pathogenic bacteria disappeared with the disappearance of the Babes-Ernst bodies. Experiments were conducted for the purpose of determining whether these bodies were immediately affected by various disinfectants. It was found that corrosive sublimate and carbolic acid produced the complete disappearance of the Babes-Ernst bodies and that these structures were also destroyed by subjection to the temperature of boiling water. Experiments in disinfecting the hands indicate that the bacteria were not always completely destroyed but that the Babes-Ernst bodies were partially or completely annihilated.

The conditions of disinfecting by means of formalin fumes, C. SPENGLER (*Centbl. Bakt. u. Par.*, 1. Abt., 28 (1900), No. 20, pp. 704, 705).—In experiments

with this substance the author found that the disinfecting power of formalin was considerably diminished in rooms filled with an unusually moist atmosphere. The most effective action of formalin in the destruction of tubercle bacillus was obtained when from 0.5 to 1 per cent of formic acid was added.

Experiments with Itrol and Actol, FRANZ (*Monatsh. Prakt. Thierh.*, 12 (1901), No. 2-3, pp. 104-107).—The author obtained good results from the use of Itrol in cases of fistula, dermatitis, and long-standing wounds. It was found that Actol could be used in intravenous injections in cases where the colloidal silver preparation had been used with good results.

AGRICULTURAL ENGINEERING.

Water measurements, B. C. BUFFUM (*Wyoming Sta. Rpt.* 1900, pp. 16).—The measurements of the duty of water in irrigation given in this article are the same as those reported in Bulletin 81 of this Office, (E. S. R., 12, p. 295), with the addition of observations during 1899 on the amount of water necessary to produce a maximum crop, and the results of tests of two subirrigation systems at the station. The results of the experiments on the amount of water necessary to produce a maximum crop were inconclusive, since the largest amount of water applied was apparently insufficient to produce this result. "Sod land required more water than was necessary on older cultivated soil, and the largest amount of water applied was not excessive."

Two systems of subirrigation have been under observation at the station for a number of years. "One of these consists of an iron pipe 2 in. in diameter and 900 ft. long, used on the campus for irrigating trees. This pipe has given very satisfactory results, but it has not been practicable to measure the amount of water used in it. The other system consists of one-half acre on the experiment farm which is underlaid with porous tile. Lines of $\frac{1}{2}$ in. tile are placed 18 in. deep and at distances of 20 ft. apart. These lines of pipe join 6 in. mains extending around the plat, which serve as feed and drain pipes." The results obtained in subirrigating wheat in 1899 are reported. The results of these experiments and of the general experience of the station with subirrigation "do not indicate that extraordinary crops are produced by this method of applying water, or that it is economical from the standpoint of the amount of water required to produce a crop. More water was used on the subirrigated land last season than on any other plat on the farm except one small field of alfalfa."

Experiments in road surfacing, C. H. PETTEE (*New Hampshire Sta. Bul.* 77, pp. 147-160, figs. 2).—In continuation of previous work (E. S. R., 9, p. 797) the author made comparative tests during 2 years of various surfacing materials, including gravel of different kinds, screened and unscreened, clay, sand, point rock, and stones 2 to 6 in. through, applied during the spring of 1898. The difference between

macadam, gravel, and earth roads is briefly explained, and the more important results of the experiments and observations reported are summed up as follows:

- “(1) Country towns should do more surfacing, using the best materials available.
- “(2) Sand should be removed from the gravel employed, and all gravel should be as uniform as possible.
- “(3) Labor-saving machinery should be utilized to reduce expense.
- “(4) Combinations of natural materials should be tried when the conditions are favorable.”

Cultivation and irrigation in the western district (New South Wales), C. H. GORMAN (*Agr. Gaz. New South Wales*, 11 (1900), No. 8, pp. 632-634).

Irrigation of oranges in Syria, M. RINGELMANN (*Jour. Agr. Prat.*, 1901, I, No. 3, pp. 91-93, figs. 5).—The use of various kinds of pumps for raising the underground water is discussed.

Treatise on the law of irrigation, covering all the States and Territories, with an appendix of statutory law, J. R. LONG (*St. Paul: Keefe-Davidson Law Book Co.*, 1901, pp. 526).

Ingenious water wheels, W. FAWCETT (*Sci. Amer.*, 84 (1901), No. 7, p. 104, figs. 5).—Descriptions are given of a number of devices for lifting water by means of water wheels and windmills in Nebraska.

Daily river stages at river gage stations on the principal rivers of the United States (*U. S. Dept. Agr., Weather Bureau Doc. 227*, pp. 83).—This is Part VI of a series of reports on river gage readings begun by the Signal Service in 1858 and continued by the Weather Bureau. It covers the years 1896, 1897, 1898 and 1899.

“River stations are maintained by the Weather Bureau for the purpose of making forecasts of river stages in the interest of navigation, and of issuing flood warnings in cases of dangerous rises. Daily gage readings are made at stations located on the various watersheds, and are collected by telegraph at 32 centers. . . .

“The tabulated gage readings are preceded by a statement which includes the locations of stations, descriptions of gages and bench marks, heights of danger lines, low-water, and flood marks, and other data, for the various river stations whose gage readings are included in the tables. The gage readings are arranged by river systems, and are preceded by two indexes—one alphabetical, with respect to the stations, and the second following the arrangement of the text.”

The hydrography of Allegany County, F. H. NEWELL (*Maryland Geological Survey, Allegany County. Baltimore: Johns Hopkins Press*, 1900, pp. 233-251, pls. 5, fig. 1).—The hydrographic features of the county are briefly described and the results of gagings of the Potomac River at Cumberland during 1895, 1896, and 1897 are reported. Estimates of the monthly discharge of the river at that point are given, with discussions of the pollution of the Potomac and its tributaries, and the utilization of the water for municipal supplies and manufacturing purposes.

On the influence of plant cover on the flow of streams, E. WOLLNY (*Meteor. Ztschr. [Vienna]*, 17 (1900), No. 2, pp. 491-504).

Second Biennial Report of the State Engineer to the Governor of Utah, 1899-1900, R. C. GEMMELL (pp. 100, pls. 7, map 1).—This report contains descriptions of plans of State irrigation works, a record of stream measurements, an account of irrigation investigations made in cooperation with this Office,¹ a brief discussion of the State irrigation laws, the provisions of a proposed law relating to irrigation and water rights, and a table showing the discharge over Cippoletti trapezoidal weirs of different dimensions.

Trials of agricultural machinery at Ultuna: Automatic drinking devices, G. TIMBERG (*Landtmannen*, 11 (1900), No. 34, pp. 549-550).

¹ U. S. Dept. Agr., Office of Experiment Stations Bul. 86, p. 197 (E. S. R., 12, p. 895).

Trials of agricultural machinery at Alnarp: Harrows and cultivators, A. SJÖSTRÖM (*Landtbruken, 11* (1900), Nos. 22, pp. 345-351; 24, pp. 383-386).

Agricultural implements at the Paris International Exhibition, 1900, F. S. COURTNEY (*Jour. Roy. Agr. Soc. England, 3. ser., 11* (1900), pt. 4, pp. 653-673, figs. 3).

Borsig electric plow (*Sci. Amer. Sup., 51* (1901), No. 1309, p. 20988).

Road making materials of Pennsylvania, M. C. IHLESEN (*Pennsylvania Dept. Agr. Bul. 69, pp. 104, pls. 13, figs. 5, map 1*).—This bulletin considers in detail the location, distribution, and comparative merits of the materials available for road making in Pennsylvania, and contains suggestions for the construction, maintenance, and repair of road surfaces.

Culverts, drainage, and road construction, W. R. GOIT (*Kansas State Bd. Agr. Rpt. 1899-1900, pp. 648-656, figs. 10*).—This is a popular discussion of the importance of good roads and a brief explanation of various methods of road drainage, construction, and maintenance.

The Laramie cement plaster industry, E. E. SLOSSON and R. B. MOUDY (*Wyoming Agr. Coll. Rpt. 1900, pp. 18, pl. 1*).—This article gives a brief description of the Laramie gypsite deposit, discusses the chemistry of cement plaster, and reports observations on the manufacture of cement plaster at Laramie, and tests of the effect of sand on the crushing strength of plaster, as well as of the effect of various retarders and accelerators on the time of setting.

STATISTICS—MISCELLANEOUS.

Eleventh Annual Report of Arizona Station, 1900 (*Arizona Sta. Rpt. 1900, pp. 138-186*).—This contains a report of the director on the work, staff, and publications of the station, including notes on additions to the experiment station farm, the date-palm orchard, range improvement, and on the needs of the station; a financial statement for the fiscal year ended June 30, 1900, and reports of the heads of departments, parts of which are noted elsewhere.

Twelfth Annual Report of Connecticut Storrs Station, 1899 (*Connecticut Storrs Sta. Rpt. 1899, pp. 223*).—A financial statement for the fiscal year ended June 30, 1899, a report of the director reviewing the work of the station during the year, and miscellaneous articles noted elsewhere.

Report of Florida Station, 1899 and 1900 (*Florida Sta. Rpt. 1899 and 1900, pp. 76*).—The report of the director deals with changes in the governing board and the station staff, the different lines of station work, publications of the station, and additions to station equipment. Financial statements are given for the fiscal years ended June 30, 1899 and 1900. Departmental reports, parts of which are noted elsewhere, are included.

Annual Report of Minnesota Station, 1900 (*Minnesota Sta. Rpt. 1900, pp. XXVII+746*).—The report proper contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1900, and a general review by the director of the work of the different departments and of the experiment farms at Crookston, Grand Rapids, and Coteau. Reprints of Bulletins 65-68 of the station on the following subjects are included: Soil investigations (E. S. R., 11, p. 1018), beetles injurious to fruit-producing plants (E. S. R., 12, p. 166), investigation in milk production, feeding dairy cows (E. S. R., 12, pp. 479, 484), and subexperiment farms (E. S. R., 12, p. 627). A meteorological record (noted elsewhere) is appended.

Annual Report of South Dakota Station, 1899 (*South Dakota Sta. Rpt. 1899, pp. 6-8*).—Brief abstracts of Bulletins 61-64 of the station and a financial statement for the fiscal year ended June 30, 1899.

Annual Report of South Dakota Station, 1900 (*South Dakota Sta. Rpt. 1900, pp. 20-34*).—A general account of the work of the station during the year is

given in the reports of the director, agriculturist, horticulturist, chemist, entomologist and botanist, and the zoologist and veterinarian. A financial statement for the fiscal year ended June 30, 1900, is included.

Annual Report of Virginia Station, 1900 (*Virginia Sta. Rpt. 1900*, pp. 14).—This includes the organization list of the station, a report of the director containing mainly a summary of the bulletins issued during the year, a financial statement for the fiscal year ended June 30, 1900, and brief departmental reports.

Thirteenth Annual Report of West Virginia Station, 1900 (*West Virginia Sta. Rpt. 1900*, pp. 24).—A financial statement is given for the fiscal year ended June 30, 1900. The report of the director reviews at some length the different lines of station work, and summarizes briefly some of the results of investigations previously reported. A table is given showing the quantity and value of commercial fertilizers sold in the State during the last 5 years. Brief statements are made on the results of experiments on the effect of pressure in the preservation of perishable food stuffs and on methods of preserving eggs.

Tenth Annual Report of Wyoming Station, 1900 (*Wyoming Sta. Rpt. 1900*, pp. 457).—This includes notes on the origin and purpose of the station, brief abstracts of the bulletins issued during the year, plans of station work for 1900–1901, reports of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1900, several articles abstracted elsewhere, and reprints of Bulletins 41–45 of the station on the following subjects: Some experiments with subsoiling (*E. S. R.*, 11, p. 1026), some native forage plants for alkali soils (*E. S. R.*, 12, p. 138), alfalfa as a hay crop (*E. S. R.*, 12, p. 430), alfalfa as a fertilizer (*E. S. R.*, 12, p. 427), and preliminary report on the artesian basins of Wyoming (see p. 1019).

Crop Reporter (*U. S. Dept. Agr., Division of Statistics Crop Reporter*, Vol. 2, Nos. 7, pp. 8; 8, pp. 4; 9, pp. 8).—In addition to statistical data on the crops of the United States in 1900, these numbers contain articles and notes on miscellaneous subjects, including the following: Cereal crops of France, sugar and rice crops of India, principal crops of Austria, the cotton-seed industry, the cotton crop of 1899–1900, the corn crop of the world, Russian cereal crops, the United States Department of Agriculture, Peruvian sugar statistics, apples in the United Kingdom, the jute crop of Bengal in 1900, the Hungarian estimate of the world's grain crops, wheat crop of Argentina, and principal crops of Germany in 1899–1900.

Trade of Denmark, F. H. HITCHCOCK (*U. S. Dept. Agr., Section of Foreign Markets Bul. 9*, pp. 88, map 1).—This is a detailed statistical review of the trade of Denmark for a number of years. The imports during the calendar year 1898 were valued at \$123,874,758, and the exports at \$87,464,660. About 90 per cent of the Danish commerce was carried on with the United Kingdom, Germany, Sweden, the United States, and Russia. The most important agricultural imports are Indian corn, butter, oil cake and oil-cake meal, coffee, and wheat. Butter is the most important article of export.

Maryland Geological Survey, Allegany County (*Baltimore: Johns Hopkins Press, 1900*, pp. 323, pls. 30, figs. 15).—This report contains, in addition to a brief introduction dealing with the physical features of Allegany County, articles on physiography, by C. Abbe, jr.; geology, by C. C. O'Harra; mineral resources, by W. B. Clark, C. C. O'Harra, R. B. Rowe, and H. Ries; soils, by C. W. Dorsey (see p. 1023); climate, by O. L. Fassig (see p. 1017); hydrography, by F. H. Newell (see p. 1097); magnetic declination, by L. A. Bauer; forests, by G. B. Sudworth; and flora and fauna, by C. Hart Merriam and E. A. Preble.

NOTES.

ARIZONA UNIVERSITY.—The last legislature gave the university \$25,000 for a library building, and \$30,000 for two years for maintenance.

CONNECTICUT STATE STATION.—W. C. Sturgis, botanist of the station, has been given six months' leave of absence.

COLORADO STATION.—George H. Glover, B. S., D. V. M., has been made professor of veterinary science. The president and secretary of the governing board and the president of the college have been reelected, the latter for a period of two years.

IDAHO STATION.—The governing board of the station, under a new law passed at the recent legislature, has been reduced to five members, and is at present comprised of the following members: President, John B. Goode, Cœur d'Alene; vice-president, Mrs. Mary E. Ridenbaugh, Boise; secretary, George C. Parkinson, Preston; J. W. Jones, Blackfoot; and Henry E. Wallace, Caldwell. Their terms of office, under the law, range from two to six years.

ILLINOIS UNIVERSITY AND STATION.—The Illinois general assembly has appropriated \$46,000 per annum for the next two years for the extension of the work of the station. The bill specifies the following lines of work: Experiments with corn, \$10,000; soil investigations, \$10,000; investigations in horticulture, \$10,000; experiments in stock feeding, \$8,000; dairy experiments, \$5,000; sugar-beet experiments, \$3,000. Any revenues which may accrue from these experiments revert to their respective funds. The college of agriculture receives \$10,000 for furnishing the new agricultural building, \$8,000 per annum for the purchase of live stock, and \$6,000 for increase in instructional work. The station chemical laboratory in the new agricultural building is now furnished and occupied. It consists of a general laboratory, a special laboratory, 1 workroom, 1 storeroom for chemicals and apparatus, and another for samples for analysis, and an office. The new building was dedicated May 21, 1901. The principal addresses were made by Prof. Thomas F. Hunt, of Ohio, an alumnus of the college, and by Hon. Joseph G. Cannon, of Illinois, and brief addresses were made by Dr. Thomas J. Burrill, Prof. E. Davenport, and representatives of various farmers' and breeders' organizations of the State. There was a large attendance from out of town, representing nearly every agricultural organization and interest in the State, among others the Illinois Farmers' Institute, the Dairymen's Association, the State Horticultural Society, the Live Stock Breeders' Association, the Corn Breeders' Association, the Corn Growers' Association, and the Sugar Beet Association. The occasion was one of general good feeling and of satisfaction at the increased facilities for instruction, and also at the largely increased funds both for instruction and investigation. The most flattering assurances were given of liberal support in the future.

NEBRASKA STATION.—A. L. Haecker has been appointed dairy husbandman on the staff of the station, having charge of the newly created department of dairy husbandry.

PENNSYLVANIA STATION.—B. P. Lundy has resigned his position as fellow in dairy husbandry to accept a position in Haddonfield, N. J. A repetition of the feeding experiment with steers made last winter, comparing the effects of feeding in pens and stalls, with and without a supply of water, has just been completed. As a supplement to this experiment, an attempt is being made to compare the value of the manure actually produced by these several methods of handling. The observations on forage plants which have been made in previous years are to be continued and

extended during the present season with special reference to their value in a system for soiling for dairy cattle.

SOUTH CAROLINA STATION.—At a recent meeting the board ordered the entire separation of college and station cattle, and decided to purchase first-class specimens of four breeds for experimental work. The veterinarian has in progress an experiment in rendering young cattle immune to Texas fever by inoculation. The experiments which the station has been making in the preparation of sweet potatoes for commerce and for army rations have proved very promising and will be continued on a larger scale.

TEXAS COLLEGE AND STATION.—At the recent session of the legislature an appropriation of \$3,000 was provided for additions to the equipment of the agricultural building, erected in 1900, which money is immediately available and will be used for class-room appliances, apparatus, and special forms of scientific equipment for the college and station, the general equipment of the building having been already supplied. A bill appropriating \$30,000 for additional State stations passed the senate and was favorably reported by the house committee on agriculture, but its final consideration was postponed until the special session of the legislature to be convened next August, as were also the appropriations for the purchase of improved breeds of live stock (\$10,000) and for erecting a veterinary-chemical laboratory (\$31,000). The Beeville Station was provided for at the former rate, \$2,500 per annum, with the privilege of using the proceeds from sales of crops and products.

VIRGINIA STATION.—John Spencer, D. V. S., of Canada, has been appointed assistant veterinarian of the station, in place of H. Bannister, resigned.

WISCONSIN UNIVERSITY AND STATION.—The legislature of Wisconsin, recently adjourned, appropriated \$150,000 for a central building for the college of agriculture. Plans for the proposed building were presented to the legislature for their consideration. There will be the general offices of the college of agriculture, several museum rooms, a library and reading room, a general audience room seating 700, and laboratories for the departments of agricultural chemistry and agricultural bacteriology. It is proposed to locate the new building on Observatory Hill near the dairy and horticultural buildings. Like the other distinctly agricultural college buildings it will be heated from a central heating plant now completed. As the building is to be provided for from funds raised by taxation, it will probably be two years before it is completed.

MISCELLANEOUS.—The following notice has been received from the Federation of Agricultural Unions in Italy (*Federazione Italiana dei Consorzi Agrari*) regarding a prize offered by the federation for a method for the determination of the fineness of flowers of sulphur and of mixtures of sulphur and copper sulphate such as are used in fungicides and insecticides: "Although of late years there has been considerable progress in the methods of preparation of the different sorts of sulphur used for combating diseases of plants, and the demand, in consequence, has greatly increased, the methods actually employed for estimating the degree of fineness of these preparations are now antiquated and leave much to be desired, especially as regards the mixtures of sulphur and copper sulphate. The Federation of the Agricultural Unions of Italy, together with the Agricultural Unions of Padua and Florence, considering the necessity of encouraging special studies on this subject, and having obtained contributions from many other agricultural unions, has now decided to open an international prize competition for the sum of 1,000 francs in gold, to be awarded to the person who discovers and makes public the best method for obtaining exact and constant results in the determination of the fineness of the flowers of sulphur and of mixtures of sulphur and copper sulphate. Competitors must send in their papers in a sealed envelope to the head office of the federation (*Ufficio direttivo della Federazione Italiana dei Consorzi agrari, Piacenza-Italy*) before March 1, 1902. The papers will be examined by a special commission to be named by the Reale Accademia dei Lincei-Rome whose decision will be without appeal. Piacenza, 1st March, 1901. E. Cavalieri, president; G. Raineri, director."

EXPERIMENT STATION RECORD.

INDEX OF SUBJECTS.

	Page.		Page.
Abattoir refuse, treatment with sulphuric acid	131	Actol, uses	1095
Abies, resin ducts and strengthening cells ..	827	<i>Adelges abieticolens</i> , notes, Conn. State	580
Abortion, contagious, in cattle, Kans	898	Adobe hole, notes, Ariz	798
notes	791	<i>Æcidium actææ</i> , notes	462
work of Prof. Bang, Mich	293	<i>Ægaleus bechuana</i> , notes	69
<i>Abrus grossulariata</i> , notes	159	Aeronautical committee, report	920
Absorption apparatus, Pélégot, modification	515	experiments	920
<i>Acacia decurrens</i> bark for tanning, Cal.	995	<i>Æschynomene virginica</i> , notes, La.	760
<i>melanoxyton</i> , rate of growth	1048	<i>Agalena navia</i> , notes	580
<i>mollissima</i> bark for tanning, Cal.	995	<i>Agaricus melleus</i> , notes	360, 464, 573
<i>pycnantha</i> bark for tanning, Cal.	995	<i>squarrosus</i> , notes	359
<i>Acanthia</i> , bibliography	867	Agave culture in Africa	1044
<i>Acarus folliculorum</i> , remedies	793	Agricultural—	
<i>Acer negundo</i> , notes, Utah	153	building at Kansas State Agricultural College	103
<i>pseudoplatanus</i> , rate of growth	1048	the University of Illinois ..	604
<i>saccharinum</i> , notes, Utah	153	colleges and experiment stations in the United States, U. S. D. A	198
<i>saccharum</i> , notes, Utah	153	education, address	599
Acetanilid for muscular rheumatism	392	in Austria	198
Acetic acid, determination, Haberland's method	214	English rural schools	698
effect on germination and growth of peas	1009	Germany	399, 900
production in milk by lactic acid bacteria	786	rural schools	199
Acetylene illumination, application to country homes	697	the United States, U. S. D. A	497
manufacture waste, analyses, Conn. State	931	International Congress at Paris	101
Acid, distribution in pears	558	experiment stations. (<i>See</i> Experiment stations.)	
phosphate. (<i>See</i> Superphosphate.)		experiments and education in the West	
production by soil bacteria, Del.	730	India	799
Acids, effect on action of saliva	1077	at Rothamsted	599
normal, preparation	715	implements at Paris Exposition	1097
preparation by electrolysis of copper sulphate	716	improvements	398
titration	308	station for testing at Paris ..	398
toxic, effect on lupines	1010	imports and exports of the United States, U. S. D. A	98, 298, 497, 778
Acorn bread, food value, Me.	78	investigations in Alaska, U. S. D. A.	630
meal, food value, Me.	78	libraries in the United States, U. S. D. A.	497
Acorns, experiments in storing	958	literature, classification, Nebr.	498
food value, Me.	78	explanation of scientific terms	199
<i>Acridium peregrinum</i> , notes	770	machinery in Denmark	296
Actinometric measurements in the Pamirs ..	725	products of Porto Rico	795
Actinometry, paper on	920	sciences, bibliographical repertory	199
Actinomycosis, inspection at Chicago stock yards	290	statistics for Great Britain	399
notes	684, 885, 892	New Zealand	898
Nebr	488	Students' Association, proceedings, Nebr	497
studies	92, 290	syndicate in France	498
treatment	790	Agriculture, hydraulic	898
		in Australia	199
		Bosnia	199

	Page		Page.
Agriculture in Denmark	98, 498	Aleurodidæ, monograph of American spe-	
Germany	98, 399	cies, U. S. D. A.	469
Great Britain	98	Alfalfa, analyses, Nebr.	442
Herzegovina	199	N. J.	378
India, U. S. D. A.	399	as a fertilizer, Wyo.	427
Norway	199	affected by alkali, Wyo.	431, 1008
Russia	1	culture, Wyo.	430
Switzerland	898	experiments	745
the Grand Duchy of Lux-		Colo	229
emburg	898	fertilizer experiments	133, 531, 641
Rio Grande Valley	397	for cows, Utah	783
Tropics	498	green manuring, Ariz.	1031
United States, U. S. D. A.	497	steers, Okla	670
International Congress at Paris	205	hay, digestibility, Kans	898
<i>Agilus anxius</i> , notes, U. S. D. A.	161	for pigs, Kans	898
<i>hilincatus</i> , notes, U. S. D. A.	161	in eastern Kansas, Kans.	898
<i>otiosus</i> , notes, U. S. D. A.	161	irrigation, N. Mex	539
<i>Agriotes lineatus</i> , notes	973, 974	Wyo.	431
<i>obscurus</i> , notes	1060	experiments	641
<i>segetum</i> , notes	973	leaf spot, notes, Conn. State	566
<i>sputator</i> , notes	1060	notes	143
<i>Agropyron repens</i> , notes, Nebr.	436	Can.	329
<i>tenerum</i> , notes, Nebr.	436	N. Mex	539
<i>Agrostemma githago</i> poisoning of cows	394	root rot, treatment, Ariz.	1055
Agrostological notes, U. S. D. A.	911	seed of different regions, compari-	
Agrostology, progress in, U. S. D. A.	421	son	457
<i>Agrotis ypsilon</i> , notes	865	weed seeds in	457
<i>Ailanthus glandulosa</i> , notes, Utah	153	seeding experiments	441
Air, composition at different altitudes	731	springtail, remedies	468
determination in water	716	Turkestan, culture, Wyo.	430
flora of semidesert region of New		notes, U. S. D. A.	329, 332
Mexico	913	Algæ, growth as affected by different sub-	
liquid, as a reagent	309	stances	314, 1014
effect on ferments	916	parasitic, of Java	461, 1057
purification by sodium dioxid	731	Alinit bacteria, nitrogen assimilation	37
soil	926	experiments	336, 338, 532, 739
respired, poisonous properties	477	N. J.	352
temperature as affected by forests	653	method of application	614
treatise	525, 676	Alizarin green B as an indicator	213
Alabama Canebrake Station, notes	600	Alkali, accumulation in irrigated soils, Cal.	923
College, notes	299	carbonates, determination in pres-	
Station, financial state-		ence of bicarbonates	819
ment	97	crucible for determination	419
notes	299, 899	determination in soils, Wyo	1022
report of direc-		effect on germination and growth of	
tor	97	plants, Wyo	1008
Albuminoids, new general reaction	419	growth of citrus fruits, Cal.	923
synthesis	310	injuries to plants	621
Albumoses, conversion into primary pro-		injurious quantities in soil due to	
teids	108	defective drainage, U. S. D. A.	523
nutritive value	478, 676	notes, Ariz.	798
Alcohol, effect on artificial digestion	477	origin and composition	621
carbon dioxid and water		resistant plants	621
excretion	981	salt solutions, evaporation of water	
lactal secretion	980	from, Wyo	1009
nutrition	980	salts, absorption by plants, Wyo.	1009
fumes as a disinfectant	991	soils. (See Soils, alkali.)	
nutritive value	780	spots, drainage, N. Mex	526
Alder, epidemic disease	360	Alkalimetry, use of succinic acid	308
green, notes	958	Alkaloids, plant	1008
white, notes	562	<i>Altiseheria luriciis</i> , notes	958
<i>Alctia argillacea</i> on grapes	69	Alligator pear, notes	451
<i>Aleurodes citri</i> , notes, Fla.	1058	<i>Allium fistulosum</i> , germination as affected	
<i>nubilans</i> , n. sp., description	1068	by light	1049
<i>vaporariorum</i> , tobacco smoke for,		Almonds, notes, Cal.	945
N. J.	146	Mich.	237

	Page.		Page.
<i>Abies glutinosa</i> , notes, Utah.....	453	Anemometer, tests, U. S. D. A.....	119, 425
<i>Alopecurus pratensis</i> , analyses, Oreg.....	471	Anemometers, installation.....	920
Alsike clover. (See Clover, alsike,.....)	471	Anemometric peculiarities, U. S. D. A.....	520
Alternaria leaf blight, treatment, Ala. Col- lege.....	552	Anemometry, U. S. D. A.....	1018
<i>Alternaria polymorpha</i> , n. sp., description ..	718	<i>Angelica roseana</i> , n. sp., description, U. S. D. A.....	24
sp., notes.....	359	<i>Angitia armillata</i> , notes.....	866
Mass. Hatch.....	253	<i>Angophora intermediata</i> , notes.....	455
<i>varians</i> , n. sp., description.....	718	<i>lanceolata</i> , notes.....	455
<i>violae</i> , notes, U. S. D. A.....	963	<i>subulatina</i> , notes.....	455
Altitude, effect on rainfall.....	1017	Angora goats, U. S. D. A.....	1077
yield of potatoes.....	636	Angoumois grain moth, notes, N. J.....	1062
Alum, determination in wine.....	823	Aniline orange, detection in milk.....	823
logwood test.....	1007	Animal diseases, atmospheric infection.....	790
Alumina, determination in phosphates ..	107, 416	control.....	395
Aluminum, determination.....	416, 418, 611	infectious, prophylaxis.....	489
phosphate, analyses, R. I.....	717	laws controlling, Va.....	597
<i>Amblyomma americanum</i> , notes.....	973	pathology and therapy.....	596
<i>hebraeum</i> , notes, U. S. D. A.....	861	text-book.....	596
transmission of heart water.....	491	industry, commercial aspect.....	678
Ambrosia beetles, notes.....	367, 975	in Denmark, Germany, and Great Britain.....	98
American Cereal Company's Quaker Feeds, analyses, Conn. State.....	70	index to literature.....	501
Poultry Food, analyses, R. I.....	282	index to literature, U. S. D. A.....	878
Ammonia, apparatus for determination in water.....	418	work of Federal Govern- ment, U. S. D. A.....	488
determination in gas liquor ..	1006	meal, analyses, Mass. Hatch.....	281
distillation in nitrogen determi- nation.....	307	Me.....	587
effect on metabolism in sheep ..	874	meals, analyses, Vt.....	472
for destroying nematodes.....	370	parasites, statistics.....	598
production by soil bacteria, Del.....	729	vs. vegetable food for poultry, N. Y. State.....	276
vs. nitrate of soda, fertilizing value.....	429	Animals, diseased, traffic in.....	994
Ammonite, analyses, N. J.....	840	feeding experiments in Canada..	178
Ammonium compounds, poisonous effect on wheat.....	717	importation without permits, U. S. D. A.....	830
copper carbonate, prepara- tion, Cal.....	975	injurious, methods of destroying ..	830
salts for nematodes.....	62, 462	law regulating slaughter.....	690
sulphate. (See also Sulphate of ammonia.)		<i>Anisopteryx pometaria</i> . (See Cankerworm, fall.)	
sulphate, change in weight on exposure to air.....	428	<i>Anopheles bifurcatus</i> , distribution.....	889
sulphate, effect on humus and nitrogen content of soils, R. I.....	727	<i>claviger</i> , distribution.....	889
sulphate, effect on solubility of lime and potash in soils ..	623	<i>maculipennis</i> , life history.....	1068
sulphate, for destroying weeds.....	249, 351, 1052	<i>pietis</i> , distribution.....	889
<i>Ammophila pruinosus</i> as an enemy of the cod- ling moth, Utah.....	267	<i>pseudopietis</i> , distribution.....	889
<i>sabulosa</i> , notes.....	469	Anopheles, notes.....	485
Amylolytic ferments in feces.....	477	resting position.....	769
Anesthetics, effect on respiration of plants. Analysis, methods. (See Feeding stuffs, fer- tilizers, foods, etc.)	112	<i>Anoplostethus opalinus</i> , notes.....	1067
<i>Anaphothrips striata</i> , notes, Mass. Hatch....	468	Antarctic regions, German expedition.....	920
studies.....	266	Anthomyia, bibliography.....	867
<i>Andropogon nardus</i> , notes.....	519	<i>Anthrenus pomorum</i> , remedies.....	272
<i>scharnanthus</i> , notes.....	519	<i>signatus</i> , notes.....	368
<i>squarrosus</i> , notes.....	519	Anthropain, notes.....	912
Anemometer, electric, for transmitting ob- servations.....	1018	<i>Anthroxanthum odoratum</i> , analyses, Oreg....	471
		Anthrax bacilli as affected by pyrocyanase. effect on leucocytes.....	1084
		liquefaction of gelatin ..	597
		resistance of spores on dif- ferent substances.....	989
		dissolution.....	989
		bacillus, variety.....	892
		carcasses, destruction.....	1088
		conferring immunity in rein- deer.....	490
		control.....	691

	Page		Page.
Anthrax, culture tests in suspected cases,		Apple, Baldwin spot, notes, N. Y. State.....	56
